Foreword

In the arena of business's social, ethical, and stakeholder consciousness, there are few topics that are more timely, relevant, and forward thinking than that of sustainable management. In the minds of most experts – practitioners as well as academics – the concept of sustainability embraces and is intertwined with a host of other highly relevant concepts such as corporate social responsibility (CSR), stakeholder management, corporate citizenship, ethics management, corporate social responsiveness, purpose-driven management, and others. These concepts overlap and intersect considerably and that is evident when you examine the Table of Contents of this volume.

Though initially thought of as a natural environment related phenomenon, sustainability now is more broadly conceived to embrace wider environments, including the economy and society. As the sustainability movement continues to grow, creative business people are developing new ways of doing business that benefits all aspects of the triple bottom line – profits, people, and the planet. Each of these is fully considered in my four-part concept of CSR and corporate citizenship to comprise economics, law, ethics, and philanthropy.

The emphasis on sustainable economic citizenship is fundamental to the success of enterprises. The economic bottom line goes beyond profits to include business's creation of material wealth, including financial income and assets. The basic economic responsibility, to produce goods and services and offer them to consumers at fair prices, is the cornerstone of modern capitalism. Related to this is the offering of jobs and positions in which employees can make a living to support their families and a decent standard of living. It is for this reason that in my writings I have placed the economic responsibility at the base of the Pyramid of CSR – it is essential for enterprises to prosper and succeed, and it forms the basis upon which all other responsibilities become possible. The alternative is job layoffs and economic stagnation. Given the economic challenges of the past decade including financial and pandemic issues, the sustainability of the financial aspects of operations have never been more important.

The social bottom line embraces a concern for the quality of people's lives and about equality between and among people, communities, and nations. The "S" in CSR is often broadly conceived, but its main focus is on people. Society today is typically thought of as the full array of stakeholders that business must think about and strategically management as it attempts to fulfill its financial role. Before sustainability became a well-known emphasis, CSR embraced the whole host of stakeholders, but the sustainability notion has focused attention

on the importance of future thinking and management of stakeholder relationships. Today, the social dimension includes all affairs and interactions present in the business-and-social relationship. Law and ethics are extremely important in the social dimension.

The third aspect of the triple bottom line is, of course, the natural environment. This sustainability focus is about the protection, conservation, and survival of the physical environment in which we live and the emphasis is on the planet. This is one of the most important facets of CSR today. Climate change seems to be the driving issue in this realm. In fact, if one considers the UN Global Compact's Sustainable Development Goals (SDGs), several pertain to the natural environment and its ancillaries including clean water and sanitation, affordable and clean energy, climate action, life below water, and life on land.

The concepts, terms, ideas, and management strategies found in this volume are exhaustive. The A-to-Z treatment of related notions in this volume exceed 700. Indeed, there is hardly an idea or thought you can contemplate that is not treated in encyclopedic form herein. The contents of this volume are comprehensive, up-to-date, and address all aspects of management and organizations. This volume has a strong set of editors and authors, and these contribute significantly to the overall quality of the book and its contents. This volume is unlike any other than is available today and should be required reading for academics, executives, nonprofit managers, and all others that are interested in sustainability in their enterprises. I am pleased to give this book my strong and enthusiastic endorsement, and I encourage all libraries to maintain an up-to-date version of this volume.

Dr. Archie B. Carroll

Scherer Chair of Management and Corporate Public Affairs *Emeritus* and professor of management *emeritus* in the Terry College of Business, University of Georgia, USA.

Coauthor of *Corporate Responsibility: The American Experience*; *Business and Society: Ethics Sustainability and Stakeholder Management*, 11 edition; and *Business Ethics: Brief Readings on Vital Topics*.

Preface

The Brundtland Report of the World Commission on Environment and Development of 1987 introduced the term *Sustainable Development* into global consciousness. The report alerted us all to the serious consequences of living unsustainably. It drew our attention to the unsustainable wrong assumptions that the yesteryears business model made in terms of everything nature has endowed our planet with. The said wrong business model assumed that all these nature endowed resources would last forever. Thus the journey to take-use-waste-and throw away commenced. It also drew our attention to the fact that *Planet Earth* does not have the capability to process the waste we generate without being sustainable with the waste. These and other facts have enabled global citizens to embark on a drive to drastically change the way we live and operate because of this generation and future generations for the better. The concept of Corporate Social Responsibility (CSR) has played a part in reorienting our understanding of what we should all be doing in our various life capacities as individuals, stakeholders, corporate entities, local communities, societies, non-governmental organizations, governments, international organizations, and all the animate and perhaps the inanimate components that make up our world. By being socially responsible and environmentally sustainable, we believe would transform and improve lives of both the present generation and future generations of man and other living objects. Of course, we are not oblivious to the fact that CSR is only a concept coined by some innovative scholars of yesteryears who were enlightened enough to want to delve deeper into the forms and shapes that business community's concern for society should take and the actions required by everyone in order to ensure that planet Earth would stand the test of time. Sustainable management requires us all regardless of our life callings to be ethical in all we do. Being ethical expects everybody to do the right things regardless of whether or not we are being watched. One might argue that, this is probably not always easy but that's always the correct thing to do, we owe it to planet Earth, this generation and future generations who would exist on this planet.

Treading the path of sustainable management in a world full of challenges would probably be like treading a difficult road. It is often argued that "all difficult roads often lead to beautiful destinations" this statement should be our assurance that, that should be the path to tread. It would help to ensure the survival of our common future as noted in the Brundtland Report 1987.

When the concept of corporate social responsibility (CSR) first came on to the corporate scene, there were some scholars who were adamantly opposed to what CSR was expecting profit seeking corporations to engage in. These scholars argued that CSR was advocating what they believed were *ultra vires* and perhaps *illegitimate actions* in terms of the mandates given to those at the helms of managing the affairs of corporations – *agents* by their owners and providers of capital – *principals*. Famous scholars such as Levitt (1958), Friedman (1962), and others in their camp were adamantly against the philosophy of CSR. It became apparent to all that these scholars were wrong with what have now transpired in the field of CSR and how it has now thrived worldwide. Nothing could have been more unsustainable in terms of their arguments on CSR. In fact, CSR is now practiced everywhere in the world – see, for example, Idowu and Leal Filho (2008) and Idowu (2021). In fact, today CSR is a legal requirement in some countries around the world. We can now be rest assured that managing sustainably is the right thing to do as depicted in many of the entries in the *Encyclopedia of Sustainable Management* (ESM).

The idea for the project on the ESM was conceived by the two Editors-in-Chief in the People's Republic of China in May 2013 when Idowu and Schmidpeter were invited by their great friend Dr. Liangrong Zu to go to China to support the setting up of a Center for CSR and Sustainability by Professor Hualiang Lu then of Nanjing University of Finance and Economics. It was in Nanjing that Idowu and Schmidpeter both resolved that that a second Encyclopedia on *Sustainable Management* would be desirable to compliment the Encyclopedia of Corporate Social Responsibility (ECSR) that was published five months earlier – in January 2013. The ESM was designed to help different stakeholders of the twenty-first century – managers, politicians, trade unionists, researchers, international organizations, academic institutions, non-governmental organizations, consumers, socially responsible investors, lenders, the media, and all stakeholders on planet Earth in the drive to support this generation and future generations that would exist on planet Earth. The ECSR was a very popular and successful project which I am personally very proud to have initiated. I am equally confident that the ESM would even be far more popular and successful than the ECSR.

The articles in each section of the Encyclopedia were written with the sole objective of satisfying the information needs of modern stakeholders, practitioners, researchers, legislators, international organizations, governments, tomorrow's business managers (students), and all those who are enthusiastic about how to manage sustainably in order to ensure the survival of our dear planet. It is hoped that this sister version of the ECSR which was supported by scholars with international experiences from about fifty nations from around the globe will further enhance our readers' understanding of what *Sustainable Management* is all about in their daily use of this reference book – the ESM.

Comments on how to improve its future editions are most welcome by the lead Editor-in-Chief. I also want to add that the publication of the e-version of

the ESM will continue, and I am therefore taking this opportunity to seek for articles on more relevant and up-to-date issues to the field sustainable management to be sent to us for processing and if found to be of good quality will be published in the e-version of the Encyclopedia as soon as they have been processed. Please email your articles to either of the two Editors-in-Chief or both of them. Thank you so much for your support.

Acknowledgements

We are grateful to a number of great people around the globe who have helped us to complete our second journey in the publication of a sister Encyclopedia to the Encyclopedia of Corporate Social Responsibility (ECSR), which was published ten years ago. Like the ECSR, when the journey for the publication of the ESM commenced, we were unsure of many things. For example, we were certainly not envisaging that it would take us a lot longer to get to the publication stage than it took us with the ECSR. But here we are it did take us a lot longer. I am however delighted that we got to the end of the journey. I must say that without the help and support of those I was fortunate to know prior to the commencement of the project and those I consequently got to know as a result of the project and the immeasurable contributions they made to the project, we would have been unable to make the publication of the ESM a reality. Some of these individuals as things have turned out; I would remain indebted to for the rest of my life simply because they have contributed immensely to an unimaginable success of the ESM. Like the ECSR, I am also proud to say that the ESM has made for me an unimaginable number of friends in at least 50 countries around the globe. I am so delighted for this. I am therefore extremely grateful to all our contributors for honoring our initial invitations to participate in this fantastic project, thank you all. I am particularly grateful to Professor Archie B Carroll who has continued to support all my projects. Needless to say, Professor Carroll wrote a great Foreword to this ESM, many thanks, Sir.

I want to start my personal “thank you” journey with my five co-editors starting with the “father” of the project Professor Nick Capaldi lately of Loyola University, New Orleans USA; my co-editor in Chief, Professor Rene Schmidpeter now based in Switzerland; Dr. Liangrong Zu, lately of the International Labor Organization Training Center, Turin, Italy, but now the President of two Global Academies – The Taoist Leadership Academy for Sustainability and Excellence and The Global Youth Leadership Academy, Italy; Professor Mara Del Baldo, University of Urbino, Italy; and Professor Rute Maria Gomez Abrue, Instituto Politecnico da Guarda, Portugal, thank you for being part of this successful project and for all your activities to ensure its successful outcome.

We are equally grateful to all the members of the Editorial Board of the ESM whose name I would like to mention here in no particular, Professor Eila Jeronen (Finland), Brian Jones (UK), Professor Berna Kirkulak-Uludag (Turkey), Kristijan Krkač (Croatia), Professor Duygu Turker (Turkey),

Professor Carmela Gulluscio (Italy), Professor Nirmala Lee (UK), Professor Ivana Mijatovic (Serbia), Professor Mirja Miklila (Finland), Professor Lars Moratis (Belgium), Professor Shuchi Pahuja (India), Professor Dirk Reiser (Germany), Professor Arto O Salonen (Finland), Professor Fabiana Sciarelli (Italy), Professor Benedict Sheehy (Australia), Professor Andrea Venturelli (Italy), and Professor Pedro Antonio Martin Cervantes (Spain). You have all in your different ways contributed to the process of ensuring that all the entries which found their way into the ESM are of acceptable quality, for this I am very grateful.

There are a few friends and colleagues of mine spread around the world who I would like to express my gratitude to; for helping me and the team in satisfactorily concluding the project, some of the names would probably be familiar to those who have read a few of our earlier CSR books: Professor Nadia Nedzel, Christopher Hutchinson, Professor John O Okpara, Professor Stephen Vertigans, Professor Stephen Perkins, Professor Malcolm Gillies, Timothy Cleary, Professor Dan Topor, Professor Adriana Burlea Schiopoiu Professor Adriana Tiron-Tudor, Professor Oana Raluca Ivan, Professor Biswanath Swain, Professor Irene Arraiano, Professor Belen Diaz, Professor Ndangwa Noyoo, Dr. Mikovhe Maphiri, Michael Soda, Benjamin Ade Aina, KC, Samson Nejo, Emmanuel Ayoola Osho, Samson Owokoniran, Jonathan Oluwasheyi Shebioba, Samuel A Olaleye, Venerable Superior Evangelist Joseph Adesanya, AVSE Yinka Odunlami, Lawrence Ojelade, Alfred K Idowu, Sola Olaluwoye, Bayo Odugbesi Assistant Venerable Superior Evangelist Olagunju, Elder Anoba, Olusheyi Bamgbose-Martins, MC Durojaiye, MC Rosemary Ogunlaja and MC Nike Oke. My sister Mrs Elizabeth Lawal and her family have been very helpful to me in my journey of life, thank you Ye Femi.

I also want to take this opportunity to thank my wife Mrs Olufunmilola Idowu, my darling son Josiah and great daughters: Rachael, Mary, Abigail, and Hannah who have continued to inspire me and support all my ventures. Thank you from the bottom of my heart, I am grateful and proud of you all for your forbearance and unflinching support.

I cannot forget all my friends and great colleagues at Springer Palgrave who have had to ensure that the process went smoothly with little or no problems, Christian Rauscher (a great friend of mine for well over a decade), Michael Hermann, Barbara Bethke, Allan Cohen, and Salmanul Faris Nedum Palli, you have all been most professional and wonderful in your dealings with all these fantastic individuals we have been fortunate to have as contributors and editors to the ESM.

I would also like to take this opportunity to thank some readers of our earlier CSR books and authors/editors of our Springer Book Series on CSR, Sustainability, Ethics and Governance who have at some point in the past contacted me to say some nice things about our books, thank you for caring and for being loyal to us; you are also part of the success story, thanks very much.

Finally, I would like to apologize for any errors or omissions that may appear anywhere in the ESM, no harm was intended either directly or indirectly to anyone.

About the Editors-in-Chief

Samuel O. Idowu is a senior lecturer in Accounting and Corporate Social Responsibility at the Guildhall School of Business and Law, London Metropolitan University, where he is currently the course leader for the MSc Corporate Social Responsibility and Sustainability and Advanced Diploma in Professional Development (ADPD) Corporate Social Responsibility and Sustainability. Samuel is a professor of CSR and Sustainability at Nanjing University of Finance and Economics, China. He is a fellow member of the Chartered Governance Institute, a fellow of the Royal Society of Arts, a Liveryman of the Worshipful Company of Chartered Governance Institute, and a named freeman of the City of London. He is the president and deputy CEO of the Global Corporate Governance Institute an international network of CSR scholars. Samuel has published over fifty articles in both professional and academic journals and contributed chapters in several edited books and is the editor-in-chief of three major global reference books by Springer – the *Encyclopedia of Corporate Social Responsibility* (ECSR), the *Dictionary of Corporate Social Responsibility* (DCSR), and the *Encyclopaedia of Sustainable Management* (ESM) and he is a series editor for Springer's CSR, Sustainability, Ethics, and Governance books. Samuel is an editor-in-chief of the *International Journal of Corporate Social Responsibility* and the *American Journal of Economics and Business Administration*. Samuel has been in academia for more than 30 years winning one of the highly

commended awards of Emerald Literati Network Awards for Excellence in 2008 and 2014. In 2010, one of his edited books was placed in 18th position out of forty top Sustainability books by Cambridge University Programme for Sustainability Leadership and in 2016 one of his books won the outstanding Business Reference Book of the year of the American Library Association. In 2018, he won a CSR Leadership Award in Cologne, Germany, and in 2019, he won the 101 Most Impactful CSR Leaders Award in Mumbai, India. Samuel is on the Editorial Advisory Boards of the *International Journal of Business Administration* and *Amfiteatru Economic Journal*. He has been researching in the field of CSR since 1983 and has attended and presented papers at several national and international conferences and workshops on CSR. Samuel has made a number of keynote speeches at international conferences and workshops and written the *foreword* to a number of leading books in the field of CSR and Sustainable Development. And he has examined on a few PhD theses in the UK, Australia, South Africa, the Netherlands, and New Zealand.

Prof. Dr. René Schmidpeter

BFH - Bern

Bern, Switzerland

René Schmidpeter is Professor at BFH Bern (Switzerland) and research scientist at the interdisciplinary academic faculty of the Parmenides Foundation in Munich. He is guest professor/lecturer in Germany, Austria, China, USA, India, Australia, and England as well as series editor for Springer's CSR, Sustainability, Ethics, and Governance book series, editor of the Encyclopedia of Sustainable Management (ESM), and editor of the Dictionary of Corporate Social Responsibility (DCSR). His research and teaching activities focus on sustainable business transformation, international perspectives on sustainability, social innovation, and sustainable entrepreneurship with special focus on the relationship between business

and society. René serves as an expert and keynote speaker in many academic, economic, and political steering committees as well as sustainability advisory boards. He is Vice President of the Global Corporate Governance Institute (GCGI) and Founder of M3TRIX/TETTRANOMICS in Cologne and Munich, Germany.

About the Co-Editors

Nicholas Capaldi is Emeritus Legendre-Soulé Distinguished Chair in Business Ethics at Loyola University New Orleans, where he also served as Director of the Center for Spiritual Capital. He received his BA from the University of Pennsylvania and his PhD from Columbia University. Previously, he taught at Queens College, CUNY, the National University of Singapore, the US Military Academy at West Point, and the University of Tulsa. In 1979–1980, he was a National Fellow at the Hoover Institution when it was Ronald Reagan’s Think Tank. He has participated in several hundred Liberty Fund conferences, and he is a member of the Philadelphia Society.

He is the founder and president of the Global Corporate Governance Institute. His principal research and teaching interest is in public policy and its intersection with political science, philosophy, law, religion, and economics. He is the author of 12 books, over 100 articles, and editor of 10 anthologies, and has served as editor of *Public Affairs Quarterly*. He is the author of the Cambridge intellectual biography *John Stuart Mill*. His most recent books are *Liberty and Equality in Political Economy: From Locke versus Rousseau to the Present* as well as *The Anglo-American Conception of the Rule of Law*.

Dr. Liangrong Zu is former senior United Nations official, founder of Global Youth Leadership Academy (GYLA) and Taoist Leadership Academy for Sustainability and Excellence (T-LASE), and Vice President of China Institute for Responsible Management Education and Sustainable Development. Dr. Zu is specialist and consultant in corporate social responsibility (CSR), business ethics, systems and design thinking for sustainable development, social innovation and social entrepreneurship, Taoist leadership and management, executive presence, etc. Dr. Zu holds PhD in business and management at Nottingham University Business School in United Kingdom. He received his master's degree in economics of education from Beijing Normal University in China.

Dr. Zu has authored and edited books with Springer, Emerald, Edward Elgar publishing, and Amazon: *The Wisdom of the Tao: A Novel Translation of Tao Te Ching with Illustrations of Chinese Calligraphy* in 2023 with Amazon; *Responsible and Sustainable Business: Perspectives from Taoism's Wisdom* in 2022 with Springer; *Responsible Management and Taoism: Overcoming Challenges in the VUCA Era* in 2023 with Emerald; *Encyclopedia of CSR* in 2013 co-editor with Springer, etc.

Dr. Zu is currently dedicating himself to writing trilogy of youth leadership development:

- *Rising from Zero to Hero: Youth's Journey to Unraveled Success in the VUCA World*
- *Rising Star: The GYLA Way to Cultivating 3Q and 3C in Youth as Future Global Leaders*
- *Rising from Hero to World-Changing Leaders: Transforming Youth's Dream into Global Influence in the United Nations*

**Mara Del Baldo**

Department of Economics, Society and Politics
University of Urbino Carlo Bo
Urbino, Italy

Mara Del Baldo is Associate Professor of Financial Accounting and Economics of Sustainability and Accountability at the University of Urbino (Italy), Department of Economics, Society and Politics, School of Economics. In 2017, she obtained the national qualification as a full professor in the Scientific Area of Accounting and Business Administration released by the ANVUR (Italian Agency for the Evaluation of University and Research). Mara has extensive experience in collaborative research, in conjunction with universities and private industry. She visited several European universities, i.e., the University of Vigo (Spain), the New Bulgarian University of Sofia (Bulgaria), the Corvinus University in Budapest (Hungary), and the University of Craiova (Romania). She lectured on invitation in various Italian and foreign conferences and universities, and she served as an external examiner of international PhD candidates (University of Ghent, Surrey, Vigo, etc.).

Mara is a fellow of the European Council for Small Business, the Centre for Social and Environmental Accounting Research (St. Andrews), the SPES Institute (Spirituality in Economics and Society, Leuven – Belgium), the AFECA (Association des Formations Européennes à la Comptabilité et à l'Audit, France), and the Italian Network on Business Reporting. She is an executive committee member of the European Business Ethics Network (EBEN), Italy, and the CRIMPI (Research Centre on Entrepreneurship and Small-Medium Firms (Italy) and the ASPI (Italian Association for the study of SMEs). Moreover, she is a member of leading Italian scientific and academic associations, such as SIDREA, AIDEA, SISR, the GBS (Study Group of Social Reporting), and the OIBR Foundation (Organismo Italiano Business Reporting). Mara is also a member of the academic advisory committee in the Global Corporate Governance Institute (USA) and global network member of Corporate Governance Experts Global Repository (Virtues Interpress).

Mara serves as a board member and a reviewer of several international journals, including the *International Journal of Corporate Social Responsibility* (Springer Open Access Journal), *Journal of Business Administration Research* (JBAR), *Journal of Modern Accounting and Auditing* (IJMAA), *Journal of Small Business Management* (JSBM), *Meditari Accountancy Research*, CSREM, BSE, and *Frontiers of Sustainability*. Moreover, she served as editorial board member of the Dictionary of Corporate Social Responsibility (Springer, 2015) that won an Outstanding Reference Book Award of the year in 2016 from the American Library Association (ALA) in Boston, MA, USA.

Her main research interests include entrepreneurship and small business; CSR and business ethics; financial, social; and integrated reporting; accounting and gender; and benefit corporation and economy of communion companies. She published in several Italian and international journals (*Accounting History*, *Meditari Accountancy Research*, *European Journal of International Management*, *International Journal of Social Ecology and Sustainable Development*, *Journal of Management and Governance*, among others), as well as in books of the Springer Series on CSR, *Sustainability, Ethics and Governance*. Among the awards received during the academic career, one can cite 2020 and 2021 Certificate of Distinguished Reviewer for the *Journal Corporate Governance and Sustainability Review*; top cited articles 2021/2022 *Journal of International Financial Management and Accounting*; Springer selection among the five most cited papers on the topic of CSR, *Journal of Management and Governance*, <https://doi.org/10.1007/s10997-009-9127-4> (October 2014).

**Rute Abreu**

[ResearcherID: N-3882-2013](#)

[Scopus Author ID: 9735451800](#)

[Ciência ID: 5016-176E-AAA4](#)

[SciProfiles: 2327785](#)

Rute is, since 1990, Coordinator Professor, with tenure, at the Guarda Polytechnic Institute, Portugal, where teaches quality, environment and safety standards, sustainability, social responsibility management, firm valuation and auditing at the master's degree and financial accounting, auditing, financial analysis, corporate finance, schedule and appraisal investment, and taxation at the undergraduate degree. Actually, Rute is the Accounting Degree Director and the Integrated Management System master's degree Director. Usually, she develops scientific activities within the Social Responsibility Research Network and Global Corporate Governance Institute. Their scientific research is based as an integrated researcher at the Center for Research in Accounting and Taxation of the *Cávado and Ave Polytechnic Institute*, Portugal and as collaborate researcher at the Center for Research in Digital Services. Rute, also, collaborates with *MackPesquisa* of *Universidade Presbiteriana Mackenzie*, Brasil.

Rute has a master's degree in Industrial Engineering from the *Universidade Nova de Lisboa*, Portugal and PhD degree in Accounting and Finance from the *Universidad de Salamanca*, Spain. Regularly, she develops scientific activities related with publication of research papers, participates and helps with organization process, all over the world, of conferences, meetings, projects, courses, and classes.

Moreover, she participates on the blind review process for several journals and helps as editor on the *Social Responsibility Journal* and the *Accounting and Management Review* of Portuguese Chartered Accountants. These examples are very relevant since all public servants are expected to promote the transfer of knowledge to the society related with Accounting Quality

System, Accounting Education (Accountant 5.0), Tax and Auditing Citizenship, Agriculture Sustainability (Olive oil in Portugal and autochthonous race (Burro-de-Miranda-AEPGA)), Management Quality Systems in Social Economy, and Performance Analysis at Beauty Firms.

AA1000 Series of Standards, The

Marek Ćwiklicki
Department of Public Management, Krakow
University of Economics, Cracow, Poland

Synonyms

[AA1000](#)

Definition

The **AA1000 Series of Standards** comprises three interrelated voluntary standards: AA1000 Assurance Standard (AA1000AS), AA1000 Stakeholder Engagement Standard (AA1000SES), both guided by the AA1000 AccountAbility Principles (AA1000AP). The AA1000AP provides generic guidelines for organizations, while other standards support implementation.

The principles-based standards present frameworks to guide all types of organizations in demonstrating accountability in the fields of leadership, responsibility, and sustainability. The AA1000 series of standards represent social and ethical accounting (► [Social Accounting](#)) processes aimed at facilitating stakeholder communication (► [Stakeholder](#)). Assurance refers to the organizational practice of evaluating performance (AccountAbility [2018b](#)) and binds the

three standards. It covers methods, processes, systems, and the data employed in the assurance process.

Key Issues

The AA1000AP consists of four principles:

- **The foundation principle of inclusivity** meaning stakeholders' participation in decisions on how to address sustainability issues (► [Sustainability](#))
- **The principle of materiality** meaning to include in all organization's actions material issues
- **The principle of responsiveness** meaning that organization has to respond to those stakeholder's issues affecting its performance
- **The principle of impact** meaning monitoring the organization's effect on the ecosystem (AccountAbility [2018a](#))

The AA1000SES directly refers to the first principle covering guidance for stakeholder engagement (► [Stakeholder Engagement](#)). The Standard defines good quality stakeholder engagement by establishing a rationale for engagement (purpose), defining the issues needed to be included (scope), and who should engage (stakeholders) (AccountAbility [2015](#), p. 15). A classification of stakeholders and addressing their interests is the first step toward engagement (Farooq et al. [2021](#)).

The AA1000AS can be employed in two ways. The first one – Type 1 – characterizes adherence to the above-listed AA1000 principles. The second way – Type 2 – additionally includes an evaluation of the reliability of the sustainability performance information (AccountAbility [2018b](#)). Type 2 represents high assurance as it is more precise in areas whereas Type 1 offers more generic coverage. It incorporates unrestricted and extensive evidence characteristics describing all organizational levels, with a very low risk of an incorrect conclusion.

Sustainability assurance is the key issue in sustainability reports (Kolk and Perego [2010](#)). It

is defined in the AA1000 as “Assurance of public disclosures on sustainability performance as well as underlying systems, data and processes against suitable criteria and standards” (AccountAbility [2018b](#), p. 24). Assurance is described as containing an established scope of engagement, clearly stated independence and impartiality, possessing the necessary competencies for assurance sustainability, exercise of due care, and planned engagement control.

Future Directions

A study confirms the need to adopt a sustainability assurance statement within national settings (Kolk and Perego [2010](#)). However, the specific factors behind the decision to undertake efforts to prepare sustainable reports are still evolving. Kolk and Perego ([2010](#)) also point out a quality issue relating to statements regarding the future introduction of mandatory standards. It is associated with a need for national requirements regarding the unification of content coverage in sustainability reports (Junior et al. [2014](#)).

The ability to build the capabilities and skills required by assurance providers is perceived as a major challenge (Leipziger [2017](#), p. 503). It refers to engagement planning, documenting the engagement, performing it, as well as its critical evaluation and reporting. This additionally covers the competencies to adhere to three main AA1000 principles: inclusiveness, materiality, and responsiveness. As the AA1000 standards concentrate on what should be reported, it needs to be more oriented toward explaining how the organization should be prepared to demonstrate adequate institutional competencies (AccountAbility [2018b](#), p. 15).

While the AA100 standards offer useful principles-based sustainability-assured guidance for integrating stakeholder engagement into organizational systems, processes, and data-usage, the above review of the limited academic literature available indicates the requirement for further development to improve accountability in the fields of leadership, responsibility, and sustainability.

Summary

The AA1000 Series of Standards are not the only guidelines for social and ethical accounting within a sustainability context (► [Sustainability Accounting](#)). The others include: Global Reporting Initiative (GRI) (► [Global Reporting Initiative](#)), the recommendation of Fédération des Experts Comptables Européens (FEE), and the International Standard on Assurance Engagements (ISAE) 3000 issued by the International Audit Assurance Standards Board.

The AA1000AS mainly differ from other sustainability standards based on the required items covered in conclusion with reference to the AA1000AP and the suggestion to include progress since the last report and areas of improvement. However, the scope of the AA1000 standards is more holistic compared to other accounting solutions, which explains its increasing popularity (O'Dwyer and Owen 2007). A study shows that the AA1000 is mainly chosen by non-accounting sustainability assurance providers, while accounting sustainability assurance providers tend to use the ISAE3000 (Farooq and de Villiers 2019). Nevertheless, compliance with the AA1000 and ISAE3000 delivers enhanced results in relation to stakeholder trust (Iansen-Rogers and Oelschlaegel 2005, p. 25). The explanation behind these findings demonstrates the complementary nature of both standards based on their different inherent focus. This supports the practice of adopting integrated reporting (► [Integrated Reporting](#)).

Abundance (CSR)

Mislav Ante Omazić¹, Mirjana Matešić² and Patricia Uroić¹

¹Faculty of Economics and Business (EFZG), University of Zagreb, Zagreb, Croatia

²Croatian Business Council for Sustainable Development (HR BCSD), Zagreb, Croatia

Synonyms

Extensive wealth; Opulence; Plenty

Definition/Description

There are three critical economic concepts or distinct branches of inquiry: scarcity, abundance, and sufficiency (Daoud 2018). Scarcity is described as a gap between a need or wants for a good (limited resource) and the theoretically unlimited wants of consumers (Benammar 1999). The present economy concept is a scarcity economy. Abundance occurs in a reversed situation, while sufficiency arises when requirements and goods are balanced (Daoud 2018). Abundance is often compared to having a relative degree of fullness or plentifulness that flows out of a deep inner sense of personal worth and security (Covey 2004). It is a model of understanding with plenty out there for everybody. The outcome of the abundance mentality in business is sharing prestige, recognition, and profits which opens new possibilities, options, and alternatives in doing business (Covey 2004).

Introduction

The concept of paradise is directly associated with the concept of abundance. After being banished from paradise, man was destined for lasting and difficult coexistence with the economic problem of scarcity (Rothbard 2006). Human civilization formed itself in a wild dance between abundance and scarcity. Humans are rarely rational and rarely

consume the optimal amount of needed resources, so they have created a world around their wants, not needs. Resources are especially accumulating in developed societies. The perception of development has led modern societies to a series of problems like the scarcity of specific natural resources and their permanent destruction, biodiversity loss, the devastation of nature, and the widening gap between the rich and the poor. Even before Richard Thaler was awarded the Nobel Prize for his work on cognitive biases affecting economic decision-making, it was evident that the rational homo-economicus that inhabits most economic models and theories could behave rationally only in academic papers. The basis of the objective approach is reason and analysis through the mind–intellect instrument in which the problem is typically placed outside of the collective self (Nevatia and Nevatia 2021). From the repeating history of conflict over obsession with material to the fact that humans are only beings producing waste to satisfy delusional wants, humans proved that they are both subjects and objects of (un)willing manipulation. Modern society is full of paradoxes, so although the population growth rate declined from 2.2% to less than 1% per year in relative terms, it continues to grow in absolute terms. That means that more and more humans are using the traditional consumer-centric linear model based on “explore-take-make-consume-throw away,” thinking and acting like resources are limitless.

The literature on abundance is relatively scarce, and just lately, it has been related to Corporate Social Responsibility (CSR). Throughout history, abundance has been a driving force behind economic development for humanity. However, it is important to acknowledge that creating a solution in one place cannot come at the expense of causing damage elsewhere. Creating new value and providing humans with products and services was the first and foremost reason for economic efforts of any kind, but it should be balanced, not maximized. Throughout human history, the desire for greater abundance has been a consistent motivator, often taking precedence over simply meeting basic needs. However,

numerous instances have demonstrated that merely achieving abundance does not guarantee success. In literature, abundance is defined as “an amount that is more than enough” or as “an establishment on a firm basis or for enduring existence” (Keyser 2022). An enduring existence depends on abundance. Keyser (2022) connects abundance with founders of new businesses and nonprofits that determine the components necessary to achieve lasting and consistent yields of high quality. It is also called a business model. A sustainable organization seeks growth in quality of impact rather than quantity. Sustainable organizations do not ignore “externalities” or consequences of business activity that impact society and the environment without affecting business operating costs. Instead, they take responsibility for their externalities so that they manage them and actively try to lower the negative impact those externalities cause, either to society or the environment. This way, key stakeholders, such as founders of these new companies and their managers, contribute to sustainable development while creating abundance. According to Keyser (2022), founders and abundance are two words that will become more and more commonly associated.

Abundance and Corporate Social Responsibility (CSR)

Abundance in sustainability means that organizations should find ways to create new value without spending too many resources. While leaders understand the importance of sustainability, they often need help translating it into action. Kiron et al. (2013) found that while nearly two-thirds of business respondents felt sustainability issues were important, only 10% of companies entirely tackled them. A key differentiator in their success was linking sustainability and business strategy. The abundance process is a continuous improvement fueled by the evolution of social, economic, and environmental issues (Friedlander 2016). Sustainable companies should create products and services that provide quality without extra

quantity. Separation of those two divides standard leaders from leaders of tomorrow or sustainable leaders. The real question is, how much abundance can be created without using extra resources? Can modern society continue developing and increasing the quality of life without disturbing more of Earth’s resources and ecosystems? Is this increase in value-creation and GDP rising possible on the constant amount of energy and resource usage?

Aziz (2018) advocates that abundance can be a new way of sustainability, covering more than just environmental issues. It could also cover human and social justice issues. Aziz (2018) proposes changes regarding the perception of ROI in business by incorporating environmental and social impact. He considers a more holistic view for measuring the “good” that a business does and the positive impact of many factors like loyalty, volunteering, engagement, retention, and many more. Companies that provide their employees with opportunities for volunteering and fundraising have 57% less turnover (the average cost of replacing an employee is 1.2 times their annual salary) (Aziz 2018). The parable of the talents shows that humans must first be willing to share to gain. It is unrealistic for society to continuously consume more value than it generates, and it is also unsustainable to persist in transferring value from one group of stakeholders to another. What Aziz (2018) advocates represent the fundamental values of the sustainability concept, where the preservation of the environment is not the only goal of sustainability. Instead, sustainability should help society find the compromise between preserving natural capital and providing benefits and well-being to all humans. Inclusion and diversity in companies and organizations can help to get closer to this equilibrium because it will give all employees an opportunity for self-accomplishment. At the same time, the data above show that companies with higher diversity among employees and management can better understand the market’s needs and provide innovation revenues. In other words, diverse companies can better understand diverse populations’ needs and create products and services to fulfill those needs.

Abundance and Sustainable Leaders/Leadership

Sustainable leaders will know how to unlock the potential in their employees and their companies and will create value for the entire value chain. Unlike classical leadership thinking, sustainable leaders will not think just of the interest of their shareholders but will strive to create value for all included in their value chain. In other words, they will be creating abundance. As Friedlander (2016) has poetically put it: “The steward with an attitude of abundance freely plants and nourishes seeds of opportunity trusting in the principle of the harvest to yield her fruit. On the other hand, the landowner, whose vision is obscured by scarcity, distrusts the vagrant elements of sun, rain, and soil that might combine to multiply his storehouse and instead keeps precious seeds locked away to rot and fertile ground to lay fallow.” The cyclical nature of abundance is shown in Fig. 1.

So, when discussing sustainable leaders who can create abundance, it is vital to understand the inefficiency of using natural capital and the number of products that are becoming waste, polluting ecosystems and the environment. In that sense, sustainable leadership imperatives should be to:

- Create a company that is creating value for all stakeholders in the value chain, not just shareholders.
- Use the company’s potential to create more efficient ways of using natural capital and resources.
- Use a company to create well-being and self-accomplishment for all employees, not just top management structures.
- Create a corporate culture that enriches not only employees but also the customers, clients, and society.
- Use the power of the corporation to educate and raise awareness on important issues like

Abundance (CSR), Fig. 1 Consists of inbound, operations, outbound, marketing, service, and unsold production (Friedlander 2015)

solidarity and responsibility for each other and the environment.

- Use a decision-making process to innovate, progress, and educate.
- Use the company potential to create sustainability in the entire value chain.

In other words, sustainable leaders will use the company's potential to create abundance. Sustainable leadership imperatives should be to create a company that is creating value for all stakeholders in the value chain, not just shareholders. However, the open question remains: is a sustainable business strategy enough to create abundance from scarcity? Is a shift in how sustainable businesses manage resources enough to make the economy and human lifestyles sustainable? Alternatively, should humans also work on a transformative change in their behavior in spending and consuming lifestyle choices? Is abundance available for everybody in the context of substantial resources and a rising human population? Alternatively, is abundance just something humans must put aside out of solidarity toward each other and out of responsibility toward the environment?

Critical Elements for Economy of Abundance

To transfer from an economy of scarcity to an economy of abundance, it is crucial to have sustainable leaders with a vision that all humans and other species on this planet will be able to progress in the present and future (Hoeschele 2010).

Hoeschele (2010) advocates seven critical elements that are crucial for an abundance economy:

1. Natural resources and land commons, are gifts of nature. No human has created them, which is why they should be treated as gifts, not as unlimited resources as in the present economy. A sustainable business should take the case for these gifts.
2. A cooperative business is a type of business where an organization is owned and led by its members who participate in the production process.
3. Energy for everyone is vital for cooperative and sustainable businesses as they should try to increase energy efficiency wherever possible.
4. The financial industry is a servant, not a master. In contrast today, financial services are the game makers, not servants, and this needs to change in abundance future.
5. Smart cities are not made to serve authorities and housing developers, but humans who live there.
6. Autonomous learning is where humans learn because they desire personal growth and development.
7. Genuinely caring for health means a shift from health care oriented on doctor's enrichment, pharmaceutical, and insurance companies to care for people's health.

Summary

The objective world subsists, functions, and plays its follies according to the temporal dominion and phenomenal laws over which man has no control – just as he has no control over laws of gravitation (Nevatia and Nevatia 2021). The generally accepted notion is that the economy operates under conditions of scarcity, whereby resources that are limited in supply are considered valuable. Paradoxically a scarcity economy leads to environmental destruction because the natural environment is treated as a free commodity. Social inequality among humans is mainly created due to the control of critical assets by a few. So, it is inevitable that society will change the present economic system that is based on the limitless consumption of scarce resources to more sustainable models. Shifting from a scarcity-based to an abundance-based economy involves altering the mindset from perceiving an infinite supply of resources to satisfy humans' desires, to recognizing that humans possess only adequate resources to fulfill our necessities. Abundance is closely related to the company's sustainable business model and society, so leaders who can change the economy and

the world with organizational abundance will redefine the new normal in the role of business in contemporary society.

[Association of Chartered Certified Accountants](#)

Definition

The Association of Chartered Certified Accountants (ACCA) is the international organization of accountants which awards the qualification of Chartered Certified Accountant, a qualification recognized throughout the world. ACCA was founded in London in 1904 and currently has approximately 241,000 members in 178 countries. The purpose of the association is to train highly professional accountants. The term chartered was awarded in 1974 by Royal Charter of the United Kingdom in recognition of the high degree of quality of qualifications. ACCA offers several certificates that fall under the scope of accounting and finance. The members of ACCA are characterized by high professional skills and high ethical qualities.

The Evolution of ACCA

ACCA was founded on 30 November 1904 when 8 accountants formed the London Association of Accountants, the predecessor company of ACCA. The early 1890s are characterized by a strong growth in members, reaching 1000 in 1910. From the early years, the company was

characterized by its intentions to go beyond national borders. In 1913, in fact, the first foreign branch was opened in South Africa. Internationalization that will materialize with greater force in the following years. In the 1930s, the first branches in Asia were opened in Malaysia-Singapore. The Asian presence was strengthened in the 1950s with the opening of other branches, such as that of Hong Kong, at the same time as the increase of the presence in Africa. In 1939, the Association of Chartered Certified Accountants was officially born as a merger of the London Association of Certified Accountants (formerly the London Association of Accountants) and the Scottish body Corporation of Accountants. The following years consolidate the role of the association in the world with the opening of new branches and the increase of members and students who use the services offered by ACCA.

Thanks to the high qualification offered to students and members, ACCA obtains important recognitions in the United Kingdom. 1974 was an important year for ACCA as it received the important recognition of Royal Charter from Queen Elizabeth II. In 1986, however, ACCA, which had more than 25,000 members, was recognized under the Financial Services Act.

The launch of the website represents another important moment for ACCA. The definition of an institutional website allows to increase the latent potential of the association. Thanks to the association's presence on the Internet, it was possible to introduce and develop the first digital services for businesses. Presence on the web is consolidated over the years reaching 2004 with the opening of ACCA connect.

Recent years have confirmed the commitment made by ACCA in professional training all over the world where it has more than 100 offices. In addition, it has actively engaged in social and environmental issues. ACCA has proved since the first years of its establishment an association with a farsighted and sensitive look at issues relating to environmental social fields. With regard to social topic, it should be noted that in 1909 Ethel Ayres Purdie became the first female accountant to be a member of an accounting association. Also in the gender field, in 1980 the first female

president of the association was elected as well as the first female president of an accountancy body. With regard to the environmental field, in the 1990s a rewarding system was introduced for environmental reports.

Sustainability According to the ACCA

ACCA has shown over the years its commitment to issues related to sustainability. His commitment has been demonstrated several times throughout the life of the association. The testimony of the continuous commitment was also demonstrated by the Queen's Award for Enterprise obtained in the sustainable development category. In terms of reporting, the first CSR report was published in 2009 in which the CSR practices carried out by the association were reported for the first time. The first integrated annual report was also published a few years later. ACCA has also become the first accountancy body to examine the integrated report within the exams of the professions.

Among the CSR practices, it is worth mentioning call for action against climate change. Through this call, the association wanted to underline the critical issues relating to climate change by asking for urgent interventions by governments and companies. In fact, climate change is one of the major megatrends to which governments and businesses should give timely responses (Cosma et al. 2022; Luo and Tang 2014; Ngo et al. 2022). The short-term trend of companies to maximize profits for shareholders could represent an obstacle to the responses of these subjects to the challenges posed by global warming (Pizzi et al. 2023). To governments, ACCA suggests using taxation as a tool to guide organizations and various subjects and support sustainable economic growth. Among the proposals suggested to businesses, ACCA suggests:

- Identify and assess risks related to climate change
- Implement environmental, social and governance (ESG) performance metrics in order to

integrate sustainability into strategic planning and strategy definition processes

- Adjust corporate governance and risk management to emerging risks and opportunities as well as rethink new business models integrating ESG issues
- Promote circular economy-oriented policies

The thought of ACCA is also expressed in the profuse commitment to zero carbon emissions and achievement of sustainable development goals (SDGs).

Summary

In an increasingly changing and complex context, the high qualification of accounting professionals represents an important driver in support of company decisions. In the 119 years since its foundation, ACCA has provided useful training to practitioners to increase specific knowledge and update it according to new challenges, as in the case of non-financial reporting. The relevance of ACCA's work is demonstrated by the presence of the association in the major international accounting forums: the International Federation of Accountants (IFAC), the Confederation of Asia Pacific Accountants (CAPA), the ASEAN Federation of Accountants (AFA), the Fédération des Experts Comptables Européens (FEE), and the Pan African Federation of Accountants (PAFA).

Acceptability of activities; Acceptability of processes; Legitimacy of operations; License to operate

Definition

Acceptability is a value-bound social concept applied commonly when referring to societal relationships between an organization and involved groups, i.e., judges that evaluate operations or actions of the unit. The acceptability of a matter reflects the values of a society at a certain point in time and place. A value refers to choices which are (1) adopted from the surroundings, (2) considered in common, (3) permanent, and (4) concerned with the defined targets (Allardt 1983).

The other value-related feature is the matter of judgment. This entails the process that a judge evaluates the value-based matter and gives standards and criteria to the matter. Fredrick (1995)

considered each person's having personal values, which characterizes values as capable of expressing relative human diversity in social time and space.

Values tend to follow new social trends. The general substances of value characterize the concept giving the changing feature to the concept of acceptability. As a value, it is relatively permanent in nature, although value changes do occur for various reasons and can operate in different directions. Changes in social, cultural, demographic, economic, and technological factors can often be identified behind the value development (Karppinen 1998). The changing nature is one of the major limitations of the acceptability concept when standardizing organizational operations and process through the third-party judgment.

The acceptance is closely related to operations that interact closely with surrounding societies. Consequently, the concept of acceptability is used in practice when referring to societal relationships within socially sensitive sectors, such as natural resources-based sectors, sectors related to basic needs, like food, water, and energy, or other type necessities, or health care and medical sectors.

Introduction

The concept of acceptability is used in practice when referring to societal relationships within socially sensitive sectors, for example, natural resources-based sectors. The consumers' and/or stakeholder' acceptance is perceived relevant for the successful business operations which is well reflected in the number of scientific researches since the early 2000s. For example, Mikkilä (2003) started to investigate the concept among practitioners within the pulp and paper industry in Finland in the later 1990s. The changing operation environment and active environmental debate surrounding the industry together with internal pressure to strengthen the quality of the production process lead to the employment of the concept when assessing future challenges related to the interaction of the industry with the society (Mikkilä 2006).

Acceptability of Natural Resource Related Operations

Mikkilä (2003) proposed the application of the acceptability of operations as an indicator of corporate social performance. Furthermore, Mikkilä (2005) provided empirical content for the acceptability of operations through a qualitative field study concluding that the acceptability of operations is an applicable indicator for corporate social performance. Mikkilä et al. (2005) tested further the indicator hypothesis by applying multi-attribute methods. Mikkilä (2006) concluded the acceptability of operations being a social value expressing a person's or group's expectations. Also, the societal debate is reflected in the acceptability characteristics. The concept of acceptability is a local and regional phenomenon based on the local and regional value base.

McGuire et al. (2017) studied social acceptability in establishing of forest-based biorefineries in Maine, USA, in order to understand general public and local perceptions of bioenergy industries in their establishment, success, and sustainability. Apollo et al. (2017) investigated the reduction of environmental degradation in the county as a result of artisan mining. The livelihood by the indigenous people may be considered generally acceptable operation. The work analyzed the feasibility and acceptability of community participation, technology, and management strategies on the reduction of environmental degradation in Taita Taveta County, Kenya.

Horta Nogueira et al. (2017) applied the concept of acceptability in reviewing the available works in the field of sustainable and integrated bioenergy, more precisely in the areas related to energy production and agricultural activity. The work outlined a supporting approach for supporting policymakers in taking decision process of deploying sustainable bioenergy systems in Latin America and Africa.

Acceptability of Food-Water-Energy Nexus

The acceptance is closely related to the basic needs-related sectors, such as food, water, and

energy, or other type necessities that interact closely with surrounding populations. For example, Bouwer Utne (2008) discussed the performance of the Norwegian fishing fleet within an acceptable level of sustainability. The outcome was acceptance criteria of a sustainable Norwegian cod-fishing fleet to enable fisheries to monitor the sustainability performance of the fleet.

MacRitchie (2014) analyzed public's views on acceptability of interventions to reduce *Campylobacter* in poultry production in the UK. Zungu et al. (2019) aim at providing nutritional recommendations in South Africa for undernourished populations by assessing the effect of *Moringa oleifera* leaf powder (MOLP) on the nutritional composition and consumer acceptability of the snack.

Availability and public acceptability of residential rainwater use in Sri Lanka was examined through a questionnaire survey indicating high acceptability of noncontact and non-intake uses, such as outdoor, toilet, and laundry uses (Takagi et al. 2019). Mirás-Avalosa et al. (2017) investigated the effect of irrigation on consumer acceptability of white wines comparing irrigated against rain-fed Albariño and Godello vines. Consumer acceptance was analyzed using descriptive and multivariate techniques.

Sustainable business models as an innovation strategy and the related consumer's acceptance in the water sector was investigated by Sousa-Zomera and Cauchick Miguel (2018). The findings showed the space to strengthen consumers' acceptance, risk perception, and confidence in decentralized approaches with the support of business models through the integration of customers. Westin et al. (2016) combined a stylized transport model of an urban road network with a model of the political process. The combined model incorporated interactions between voters, citizen interest groups, and politicians to explore the political acceptability for efficient transport policies.

On example of the application of acceptability in the energy sector comes from Dreyer et al.'s (2017) attitudes' and behaviors' assessment related to tidal energy. The study outcome that higher levels of perceived benefits and climate change

beliefs were associated with increased acceptability of and support for tidal energy whereas greater perceived risks were associated with decreased acceptability and support. The conceptualization showed the characters of acceptability as an attitudinal construct, supporting a behavioral construct. Liu et al. (2019) compared the acceptability of renewable energy projects in the Netherlands and China. The work concluded the public acceptability being lowest when people had low trust in responsible agents and when people could only influence minor decisions regarding the project both in the Netherlands and China.

Acceptability Research Within Medical Sciences and Treatments

Health care and medical sectors are socially very sensitive areas of operations. Logically, the research field investigates largely the social acceptability of practices. The research has been significantly active in the late 2010s indicating the increasing popularity and applicability of the concept of acceptability in this context.

One of the newest works reviewed acceptability of financial incentives directed to patients for health-related behavior change (Hoskins et al. 2019). Burnett-Zeigler et al. (2019) studied the acceptability and feasibility of a mindfulness-based group intervention for socioeconomically disadvantaged women in an urban community health center with qualitative research techniques. Mock and Sethares (2019) tested concurrent validity and acceptability of the single item literacy screener, functional health literacy, and the newest vital sign in hospitalized adults with heart failure. Rush et al. determined feasibility, acceptability, and initial efficacy of the inhibitory-control training for drug use disorder and contingency management.

Acceptability Within Quantitative Research and Performance Techniques

The concept of acceptability can be studied both quantitatively and qualitatively. For example, Gall

and Rodwell (2016) considered the concept of social acceptability informative and relevant within the conservation of natural resources when applying Q methodology, a quantitative approach to reveal stakeholder perspectives, to assess social acceptance in the context of a marine protected area with fisheries and conservation management goals.

The concept of acceptability was applied also in evaluating performance appraisal techniques. An appraisal system has been judged traditionally according to its reliability and validity indexes, but recently the user acceptance has been considered critical to a system's successful implementation (Hedge and Teachout 2000). Song et al. (2017) applied a stochastic multi-criteria acceptability analysis to present a holistic measurement of the country-specific energy performance.

Conceptual Framework

The acceptability of operations has been largely applied in various research fields when investigating involved people's perceptions during the 2000s. The acceptability of operation relates closely with the concept of legitimacy and institutional behavior. The acceptability of operations refers commonly to the practical and operational use meanwhile the legitimacy has been applied widely by scholars. Acceptability of operations by the engaged groups, commonly stakeholders, provides a license to operate for an organization. This reflects the organizational behavior institutionalized by the Institutional organization theory (e.g., Powell and DiMaggio 1991) that the dimensions of the operation environment of an organization, such as social, economic, and political factors, build an institutional structure within which the actor engage specific types of activities.

Summary

Acceptability is a value-bound social concept being subject to acceptance for some purpose.

The concept can be considered as a value that changes in time and place. The changing nature is one of the major limitations, especially when assessing the acceptability of an issue, operation, process, protocol, etc. The issue judged acceptable yesterday, may get a different status today and tomorrow.

The acceptance is closely related to operations and procedures that interact closely with surrounding societies. Consequently, the concept of acceptability is used in practice when referring to societal relationships within socially sensitive sectors, such as natural resources-based sectors, sectors related to basic needs, like food, water, and energy, or other type necessities, or health care and medical sectors.

The research started to emerge in the early 2000s. The acceptability of operations has been largely applied in various research fields when investigating involved people's perceptions. The concept has been studied both quantitatively, qualitatively, and with mixed methods. The number of scientific works has increased significantly towards the end of 2010s indicating the popularity and applicability of the concept both among scholars and practitioners.

Synonyms

Open access economy; Resource-based economy;
Trust economy

Definition/Description

The access economy is based on the idea that we all own certain assets or services, but we do not use them all the time. So why not share them with others who need them? An access economy is a digital platform that allows community members to rent assets temporarily, as required. It emerges when access to a specific product or service becomes easy to use, cost-effective, and reliable enough that the motivation to own that product or service disappears. Different consumers and customers, from individuals to business entities, from micro to large businesses coming from developed and developing countries, can share unutilized resources, products, and/or services by means of a third-party provider, typically an app or digital platform. This enables closed community members (people and organizations) to earn financial compensation from underutilized resources.

Introduction

There are different strategies to fight overconsumption or harmful impact consumption from restrictions of advertisements to building

consumer's awareness on how, when, and where they are consuming products and services. But the most critical question is why? Why are we, as reasonable beings (*Homo sapiens*) trying to own stuff, we do not need permanently (sometimes even on temporary basis)? Why are we turning expensive living spaces, for which we sacrificed ourselves, into storage space? Why are we overproducing and overconsuming? Why do we own things, instead of sharing them in common or providing access to them?

The idea of the access economy refers to a wide range of possibilities that may be either more commercial or more social, sustainable, and democratic. The access economy, in recent years, has been surrounded by various opposing views, encompassing the idea that it contributes to a decentralized, just, and sustainable economy, as well as opposing views that it leads to the development of an unregulated market (Kumar, 2017). It is a stream of new companies that connect consumers to service providers or product owners for transactions using information and communication technology. Often is described as a novel, turbulent, and innovative feedback to overconsumption and underutilization of assets and resources (Findlay 2018). Access economy empowers individuals to achieve a more sustainable future while also changing attitudes about responsible consumption of goods and services (Albinsson & Perera, 2018). Simply said, the access economy is a distinctive business model that boosts the utilization of goods and services (Kumar, 2017).

Most of human history has been about acquiring and possessing goods and services, but recent trends have moved consumer preferences toward permanently sharing things we do not need. The value here is created from the fact that many resources humans own, are acquired to satisfy infrequent demand but are otherwise poorly utilized (for example, the average car in the USA is used less than 5% of the time) (Benjaafar et al., 2019). Sharing is a powerful concept that is as old as humanity and can be found everywhere (Bratianu, 2015). The act of sharing requires giving something that we have to others for their use and vice versa (Belk, 2007). A sharing economy is a set of practices that, mainly through technology,

allow participants and businesses to share access to goods, services, and experiences. Access economy platforms are typically described as temporary, on-demand transactions that occur over a short period through digital platforms (Bardhi & Eckhardt, 2012). Platforms are also described as organizational forms that solve the problems of delivering a good or service, clearing transactions (usually payment) between sellers and buyers, and creating trust between these parties (Munger, 2021). Sharing economy is widely defined as broad access to various products or services without the need to possess specific assets, appropriation of goods, and the exchange of intangible assets (Geissinger et al., 2022, citing Botsman & Rogers, 2010). These novel business opportunities caused a significant change in the understanding of how we as a society create value and our motivation for ownership.

Considering this, it can be concluded that several concepts exist simultaneously for this phenomenon (Fig. 1). The first is a collaborative economy, characterized as a marketplace in which buyers rely upon and meet their needs through direct interaction, as opposed via large

companies. The gig economy is a marketplace constructed of flexible, nonpermanent, or freelance jobs connected through online platforms with customers. The platform economy is the shift for businesses to move toward and in favor of digital platform business models (Govender, 2021). The on-demand economy is defined as an activity created by digital marketplaces to answer consumer wishes through prompt access to goods and services (Denning, 2014). The trust economy provides customers the possibility to control their data. The peer-to-peer economy is exemplified by the concept of transactions of goods or services between two customers without intermediaries (Pereira, 2020). The last one is sharing economy, characterized by the concept of shared assets and services between people (Govender, 2021) (Fig. 1).

Comparison Between Access and Conventional Economy

In recent years, the access economy has been growing in popularity as an alternative to the

Access Economy (Ethics),

Fig. 1 Concepts of the phenomenon. Names for this phenomenon include collaborative consumption, access economy, gig economy, platform economy, on-demand economy, trust economy and peer-to-peer economy, and sharing economy (Govender 2021)

traditional model of ownership (Bratianu, 2015). In the access economy, people consume goods or services that are owned by someone else (Govender, 2021). This shift from ownership to access is becoming increasingly popular, especially among younger generations who prioritize experience and performance over possessions (Denning, 2014). Additionally, the access economy is often seen as a more sustainable and environmentally conscious way of living. With the help of information technology, the access economy can utilize resources that would otherwise go unused. Comparatively, the traditional ownership model often results in wasted resources (Govender, 2021) (Fig. 2).

The access economy deals through the short-term rental of one particular service or product, while on a conventional two-sided business model, market revenues are generated through sales. Regardless whether it is selling goods or services, access economy is mainly service-focused, in which providers are looking to carry out higher service quality, while

conventional markets go for sharpened product quality. Service quality is essential for the access economy because the main focus is increasing the number and quality of interactions between involved parties (Choudary et al., 2016). In a conventional two-sided market, there is no face-to-face interaction with the customer needs, but in an access economy, face-to-face interaction with customers is crucial. Also, in an access economy, it is normal to have a homogeneity of services under one service provider (for example, Uber and its transportation service). Comparing the risks associated with participating in the access economy and the conventional one, the risk is more significant in the access economy due to the lack of regulations (Kumar, 2017). The access economy represents a variety of activities that are placed in four categories – the first one is the recirculation of goods, the next one is increased use of durable assets, the third category is an exchange of services, and the last one is sharing of productive assets (Ravenelle, 2019).

Access Economy (Ethics), Fig. 2 The access economy business model. The model of the shared or access economy is made up of a business enabler acting as an arbitrator

between the suppliers of an underutilized good or service and customers who demand those (Kumar, 2017)

Product Categories in the Access Economy and the Benefits for Consumers

Govender (2021) defines access economy as a system of economic activity based on shared access to goods and services, along with collaborative production. The main characteristic of the access economy is that it is built around the sharing of resources and assets among peers, which are often underutilized. This includes everything from cars and bicycles to storage space and office equipment. In recent years, the access economy has grown rapidly, with many new businesses and platforms emerging to facilitate this type of collaborative peer-to-peer consumption.

Four main types of access economies have emerged: ride access, space access, book access, and music access.

- Ride access refers to a system where people can access different vehicles for transportation, from cars and bikes to motors and scooters or other modes of transportation (Govender, 2021). Ride-sharing is an innovative on-demand transport service that aims to promote sustainable transport, reduce car utilization, increase vehicle occupancy and public transport ridership (Mitropoulos et al., 2021). One aspect of ride sharing is apps like Uber, Taxify, Curb, or Bolt, which connect drivers with people who need a ride and market themselves as taxi replacement service. Rather than owning a car, customers can experience driving on a short-term basis whenever they need a vehicle and let others drive them when they need them. Another aspect is car-sharing models like Zipcar, Getaround, Lyft, and RubyRide, where you temporarily access a car and you drive yourself. Ride-sharing models make value to consumers and influence local transportation (Chen, 2009). There are many ride-sharing advantages like no maintenance cost, no underutilization of vehicles, no need for parking space, no need for insurance costs, and a pay-per-use model. Bicycle-sharing is a service that provides access to bicycles. The key benefits of participating in bicycle-sharing platforms and apps like Ofo, LimeBike, and Mobike, are the potential to reduce the number of cars on the road, navigate traffic congestion, reduce fuel consumption, reduce carbon emissions and potentially the cost of travel (Govender, 2021). Bicycle-sharing allows a consumer to collect a bicycle on loan from one location and return it to another short-term destination (Govender, 2021). It is interesting to mention examples of the access economy in China, where instead of countless number of bikes in cities, Chinese platforms and apps are using AI and big data technologies to identify spots with the most significant demand (Ma, 2020). Besides apparent benefits connected to environmental protection like reducing the number of bikes and cutting pollution in cities, other benefits include no longer cluttering with discarded bikes, availability of bikes during rush hour, and improved health for millions, not to mention new companies and employment.
- Models of access to space vary depending on their purpose, so there are models related to access to accommodation, space for work, storage space, and so on. The most popular is the model of accommodation access, where people rent out their homes or apartments to travelers (Govender, 2021). This is usually done through digital platforms like Airbnb and Vrbo, which allows people to search for and book rooms or entire homes in different locations around the world. The literature argues for both positive and negative socio-cultural, economic and environmental impacts emanating from the tourism and hospitality businesses and value chains that are dependent on AirBnB and other online platforms (Hall et al., 2022). Positive sides to not owning a property, like cost-effectiveness, flexibility, ease of use, and has no maintenance, among others. In addition, accommodation-sharing travelers could experience a range of destinations and accommodations worldwide.
- Book-access refers to a service that provides access to books online. It is a system where people can borrow and lend books to each other instead of buying books they need

- (Govender, 2021). This is typically done through online book libraries, like Little Free Libraries, BookMooch, and BookCrossing.
- Music-streaming platforms allow users to listen to free music or subscribe for a monthly subscription for a fee (Ma, 2020). Popular examples of music-streaming platforms include Spotify and Apple Music.

There are many benefits associated with the access economy. For example, it can help reduce traffic congestion and pollution, and save people money on ownership and maintenance costs. Additionally, the access economy often leads to the creation of new jobs and businesses. However, some challenges are associated with the access economy, such as a lack of regulation, standardization of quality, and the potential for abuse by platform providers. There are a few more examples of the access economy worth noting:

- JustPark is an online digital platform and mobile app that matches drivers with parking spaces.
- Poshmark is an online digital platform for new and used women’s fashion clothing and accessories and other verticals like home décor.
- Stashbee, the online digital platform, is specifically designated for sharing storage areas.

- Spinlister is an online digital platform connecting sporting equipment owners with short-term renters.
- SharedEarth is an online digital platform that connects landowners with gardeners and farmers.
- Camp space is an online digital platform facilitating authentic camping experiences on 1000 microsites.
- TaskRabbit is an online and mobile marketplace that matches freelance labor with local demand, allowing consumers to find immediate help with everyday tasks.

The sharing economy has revolutionized our way of life and work, and its growth will continue in the years to come. As more and more people adopt this way of living, it is important to be aware of the pros and cons of the sharing economy (Table 1).

Ethics in the Access Economy

The concept of trust is critical to the access economy (Ravenelle, 2019). The term “trust” has a variety of meanings. In the access economy, it denotes how much a customer trusts someone or something (Slee, 2015). Customers are more likely

Access Economy (Ethics), Table 1 Advantages and disadvantages in access economy

Advantages		Disadvantages	
Service providers (businesses)	Users	Service providers (businesses)	Users
New business models Efficient technologies Growing of new employment areas Possibility to find parallel work Flexible working hours Free and attractive compensation models Additional earning potential Commodification of excess capacity	Accessibility Attractive prices Larger offer of products and services Reducing environmental impact Consumer comments via the Internet, transparency Earning potential	Lack of legislative regulation Possibility of unfair competition Unclear taxes practise Heavy reliance on technology Lack of consumer loyalty Modifies customer wishes Unclear quality control	Risk of fraud and scams Lack of guarantee Lack of consumer protection (privacy and safety concerns) Commercialization No ownership on permanent basis Unclear transaction costs

The examples of successful companies show that various advantages follow the new business model, but there are also some disadvantages for users and businesses (Collins, 2021)

to buy products or services that they have come to trust. Customers are readier to make purchases if they feel secure about the brand. Trust will influence customers intentions favorably, which is essential for purchase. The greater the level of trust, the more favorable the desire to use a consumption mode is. To create a digital recreation of neighborly interactions, social media companies like Facebook and Google use provider accounts to verify identities (Stone & Hernandez, 2013). Every access to a digital platform, by default, demands that users create a genuine profile with personal information, and service enablers work to gather data on people's online character from their social media presence (Ravenelle, 2019). Although the access economy has many advantages, it also contains several drawbacks, such as tax evasion, skyrocketing property prices, job and wage insecurity, and so on. The access economy concept has historically masked exploitation, and significant division of power in the digital economy (Ahsan, 2018).

EU Perspective on the Access Economy

The European Union has established two primary lines of action to stay globally competitive: continuing digitization and environmental protection. The access economy best combines these two strategic concepts by giving people services and products when they need them and how much they need them, thus increasing market efficiency and effectiveness by optimizing the number of products and services in circulation. Peer-to-peer sharing of products and services is an as old concept as human existence. However, recent technological advancements have made it more accessible by lowering the associated search, and transaction costs (Benjaafar et al., 2019). On the one hand, the human race has made incredible progress over the past 100 years as our increasingly digitized world is rapidly developing under the influence of new technological opportunities such as the Internet of Things (IoT), Artificial Intelligence (AI), augmented reality (AR), big data, blockchain, and crypto currencies, among others; on the other, there is increased awareness of the negative

human impact on the environment and ubiquitous societal trends.

Access economy is not defined in EU legislation, but it has been the subject of various studies undertaken by the European Commission and the European Parliament (Weitzenboeck, 2022 citing Abadie et al., 2016; Dervojeda et al., 2013). The access economy is a new economic paradigm changing companies and customers based on mutual trust. It has been said that access is the future of business because it creates new services that enable a new generation of entrepreneurs to flourish.

The access economy is a new theory emphasizing access to assets or resources rather than ownership. It promotes a lifestyle centered on maximizing resource usage, which results in long-term cost savings for consumers. This implies that the consumption model of clients will shift because of the access economy. Businesses selling access rather than property are popping up all over.

The access economy, as defined by Accessibility for the Visually Impaired (2011), promotes more adaptable and flexible organizational structures built on networking architecture and aided by digital technologies (Ravenelle, 2019). Uber, AirBnB, Netflix, and Spotify have demonstrated that the access economy is a valid model for growth and success. The access economy is changing how we think about access and ownership, creating a new way of doing more sustainable business for our planet.

Summary

The access economy term is described along with all the features of the business model and compared with traditional market models with particular emphasis on the ethical dimension. In a highly networked modern world, people do not need ownership and overconsumption of things and/or services but accessibility, usage, and experience. Access economy can be described as an Internet-based business model in which providers of various items and services, such as employment, transportation, tourism, workspace, music, finance, or durable-goods lending

(demand), connect. Access economy business models significantly impact the market, society, and environment due to their drastically reduced transaction costs in digital environments. They compete with existing service providers in their industries (e.g., taxi services, vehicle rentals, or space access), impact workers (e.g., their skills, income, legal issues, and way of working), and provide consumers with alternatives (e.g., through storage-sharing rather than buying a property). Therefore, the access economy has already gained considerable attention from business, economic, environmental, and social science research.

Description

In its broadest sense, accountability in the corporate context refers to the extent to which corporate agents, primarily managers and directors, take responsibility for actions taken within the corporate. Responsibility for the consequences of corporate actions extends to stakeholders including shareholders, loan creditors, trade contacts, employees, and society. Accountability is an area of corporate governance which has enduringly drawn the attention of policymakers and scholars. Often viewed from a financial perspective, accountability has been promoted in UK best governance practice guidelines since the publication of the *Cadbury Report* in 1992. Over time, the need for accountability to parties beyond those with financial interests in the corporate has been recognized, and the standards of accountability expected in the corporate environment have extended and increased. This entry reviews the evolution of the concept of accountability within the UK corporate governance regulatory framework and considers the extent to which the current guidelines serve to promote accountable corporate activity in an inclusive and sustainable manner.

Introduction

Corporate governance may be viewed as a system which ensures that companies discharge their accountability to all their stakeholders (Solomon 2007). Accountability is a subset of governance and involves the monitoring, evaluation, and control of organizational agents to ensure that they behave in the interests of shareholders and other stakeholders (Keasey and Wright 1993). As such, a key premise of good governance is that management and directors should be accountable for their actions. While a strictly financial view of the corporate focuses primarily on accountability to shareholders, it is claimed that corporate development and shareholder returns may only be achieved if corporates ensure a level of accountability to all of their stakeholders (Stoney and Winstanley 2001). For over two decades, an enduring desire for corporate accountability

among investors and other corporate stakeholders has motivated continual development of guidelines and recommendations on best practice in corporate governance in the UK. Such recommendations seek to foster the principle of accountability among corporate boards without enforcing it upon them through the legal system. Best practice recommendations of the 1990s place a palpable emphasis on accountability to the shareholder; this is particularly true of the *Cadbury Report* and the *Greenbury Report*.

The Cadbury Report

The *Cadbury Report* captures the essence of accountability in corporate governance in stating that shareholders, as owners of the corporate, elect the directors to run the business on their behalf and hold them accountable for its progress. The issue for corporate governance is how to strengthen the accountability of boards of directors to shareholders (para. 6.1). Since the committee's terms of reference were primarily related to the financial aspects of governance, much of the recommendations made within the report are directed toward the role of the board, the audit committee, and the independent auditor in ensuring financial accountability to the shareholder. The report advises that the most direct method of ensuring that corporates are accountable for their actions is through open disclosure by boards and audits carried out against strict accounting standards (para. 5.2). This is promoted and strengthened through properly constituted boards, a separation of the roles of chairman and chief executive, audit committees, vigilant shareholders, and financial reporting and auditing systems which provide full and timely disclosure (para 7.2).

The Greenbury Report

The board's role in assuring accountability with regard to directors' remuneration is considered in depth in the *Greenbury Report* (1995). Despite its origins as a response to public concern regarding

increasing levels of executive pay which coincided with redundancies and wage reductions among low- to middle-income earners, the *Greenbury Report*, like the *Cadbury Report*, converges largely upon accountability to the shareholder. The guidelines recommended within the report consider the remuneration committee as the body with primary responsibility for ensuring accountability with respect to executive pay (para 4.3). Disclosure is viewed as the main mechanism through which such accountability may be exercised (paras 5.2–5.3). Linking pay to performance in a manner that reflects the corporate's position within an industry is also strongly encouraged as a means of justifying the levels, and structure, of the remuneration package awarded to individual directors (paras 6.6–6.7; 6.16).

Both the *Cadbury Report* and the *Greenbury Report* are considered to have led to enhancements in accountability (*Hampel Report*, para. 1.1). The emphasis placed in the respective reports on the roles of the audit and remuneration committees in ensuring accountability to the shareholder is strongly reflected in the *Combined Code* on Corporate Governance of 1998 (FRC 1998).

The Higgs Review

The shareholder-oriented perspective on accountability persists to some extent in the *Higgs Review* (2003), describing corporate governance as providing “an architecture of accountability – the structures and processes to ensure companies are managed in the interests of their owners” (para 1.5). The *Higgs Review* considers how effective board processes can support accountability such that good governance is ensured, noting that a “progressive strengthening of the existing architecture is strongly desirable, both to increase corporate accountability and to maximise sustainable wealth creation” (para 1.13). While acknowledged in the *Cadbury Report* to an extent, the *Higgs Review* underlines shareholders' responsibility to actively engage with the corporates in which they invest to ensure accountability is delivered to them (para 17.8).

The Smith Report

The *Smith Report* (2003) makes recommendations concerning the accountability of the external auditor to the audit committee and the accountability of the audit committee and the board to the shareholders. These recommendations place particular weight on the independence of both the external auditor and the audit committee so as to strengthen such accountability. With regard to the activity of the audit committee, the *Smith Report* recommends committees meet at least three times in the year (para 3.5) and monitor the integrity of the corporate financial statements, the effectiveness of internal financial control and risk management systems, and the effectiveness of the corporate's internal audit function (para 2.1). However, it is made clear that it is the board as a whole who is accountable to the shareholder for producing accurate, compliant, financial statements (para 5.2). With regard to the external audit, it is advised that the audit committee makes recommendations to the board regarding the appointment of the external auditor (para 5.15); approves the auditor's remuneration and terms of engagement (para 5.19); ensures rotation of the external auditor (para 5.25); ensures the external auditor's independence, objectivity, and effectiveness; and develops and implements policy regarding the external auditor's supply of non-audit services (para 5.26). Recommendations put forth in the *Higgs Review* and the *Smith Report* were incorporated in the revised *Combined Code* (FRC 2003).

The Combined Codes of 2006 and 2008

The 1992–2003 period witnessed a continued strengthening of guidelines aimed at encouraging appropriately structured and skilled boards, which were sufficiently active to ensure accountability to the shareholder. Changes made to the *Combined Code* in 2006 and 2008 tend not to place any significant additional onus on the board of directors. Revisions to the Code in 2006 largely serve to facilitate the shareholder in requiring accountability from the board by setting out guidelines on

shareholder voting by proxy (FRC 2006: Provisions D.2.1. and D.2.2). The revised Code of 2008 introduces greater flexibility for board by removing the restriction on directors from serving on more than one FTSE 100 board and permitting chairmen in smaller corporates to serve on audit committees. In this regard, the guidelines appear to introduce something of a balance between the board's responsibility to ensure accountability to shareholders and the need for a board to be structured in a manner that best suits the size and nature of the business (FRC 2008).

The Walker Review

In the wake of the Global Financial Crisis of 2008, the consequences of short-term-oriented risk-taking behavior became starkly apparent. The *Walker Review* (2009) noted the need to ensure that boards are “equipped and driven to focus more effectively on the core elements in the wide array of accountabilities that they already have” (para. 2.12). The review highlights nonexecutive directors' role in holding executive directors to account in strategic decision-making with respect to the sustainability of strategies pursued (para. 3.9). While initially directed toward the banking and financial services industry, the recommendations of the review led to the replacement of the *Combined Code* with the *UK Corporate Governance Code* (FRC 2010a) and the accompanying *UK Stewardship Code* (FRC 2010b).

The UK Corporate Governance Code and the UK Stewardship Code

There are a number of notable aspects of the *UK Corporate Governance Code* (2010) which serve to reinforce the spirit of accountability by the board and management (FRC 2010a). The *Walker Review's* strong emphasis on regular board refreshment as a means of sustaining board accountability is reflected in the Code, which requires all directors of FTSE 350 companies to stand for annual re-election (Provision B.7.1). In light of the lessons learned from the financial

crisis, the Code sets out the board's responsibility to determine the nature and extent of significant risks it is willing to take (Principle C.2). In this respect, the FRC expresses the view that clear lines of accountability throughout the corporate are essential for effective risk management (FRC 2011). A large degree of responsibility is placed on nonexecutive directors to hold themselves accountable for risks taken by the corporate; it is recommended that they satisfy themselves that financial controls and systems of risk management are robust and defensible (supporting principle A.4). Yet, the board as a whole is considered accountable for risk-taking within the corporate. Under provision C.2.1, the board should, at least annually, conduct a review of the effectiveness of the corporate's risk management and internal control systems and should report to shareholders that they have done so. The Code also echoes the recommendations of the *Walker Review* and a general post-crisis focus on long-term value creation. The Code is presented as being "based on the underlying principles of all good governance: accountability, transparency, probity and focus on the sustainable success of an entity over the longer term" (FRC 2010a, Governance and the Code, para 4). This view of governance might be considered more prescriptive and outward-looking than that taken in the prior *Combined Code* (FRC 2008): "Good governance should facilitate efficient, effective and entrepreneurial management that can deliver *shareholder value* over the longer term." Nonetheless, the provisions of the *UK Corporate Governance Code* (FRC 2010a) remain predominantly focused on accountability to the shareholder and offer little guidance on accountability to other stakeholders of the corporate.

The introduction of the accompanying *UK Stewardship Code* marked a significant broadening of the concept of accountability from the perspective of codes of best practice. Before this, guidelines aimed at promoting accountability focused almost exclusively on the relationship between the board and the shareholder. The *UK Stewardship Code* (FRC 2010b) aims to make investors more accountable to their clients and beneficiaries with a view to improving long-term

returns to investors (*UK Stewardship Code*, Preface). The Code sets out that institutional investors' duty is to act within the interests of their beneficiaries and offers guidance on resolving conflicts of interests which may arise between institutional investors and their beneficiaries, particularly in respect of voting at AGMs of parent and client corporates (Principle 2). Institutional investors are advised to make disclosures regarding their activities regarding voting and engagement with investee firms so as to enhance their accountability to their beneficiaries (Principles 6 and 7). The Code also guides institutional investors in holding the boards of investee corporates to account through monitoring and dialogue (Principle 3), intervention when necessary (Principle 4), and collaboration with other investors (Principle 5).

The *UK Corporate Governance Code* has undergone revisions biennially since 2010. Revisions made to the *UK Corporate Governance Code* in 2012 may be seen to increase the level of accountability expected from boards, and in particular audit committees, to shareholders (FRC 2012). Principally, audit committees in all firms are required to disclose to shareholders, a detailed narrative of how they adhere to their responsibilities (Provision C.3.8). A palpable onus is placed on the board to make themselves accountable for overseeing the sustainable performance of the corporate in the 2014 edition of the Code (FRC 2014), which advises the publication of a clearer and broader view of solvency, liquidity, risk management, and viability (Provision C.2.1). Boards must identify any material uncertainties to the corporate's ability to continue to adopt the going concern basis of accounting over the next year (Provision C.1.3).

Following the introduction of a new EU regulatory framework on audit reform in 2016, the Directive 2014/56/EU and Regulation 537/2014, many of the changes which emerged in 2016 are manifest in the FRC's *Guidance on Audit Committees* (FRC 2016a), published separately to the *UK Corporate Governance Code* (FRC 2016b). Accountability to the shareholder is strongly encouraged in the guidance. The audit committee should include in the annual report, a section, signed by its chairman, explaining the nature of

its role to shareholders (para. 80). The chairman of the audit committee should be present at the AGM to answer questions on the audit committee's activities and matters within the scope of the audit committee's responsibilities (para. 85). The emphasis placed upon assurance of the financial sustainability of the corporate is carried through in the guidance which states that, unless a separate risk committee is in place, the audit committee should review and recommend to the board the disclosures included in the annual report in relation to internal control, risk management, and viability (para. 44).

Notwithstanding, the heightening of the standards of accountability expected from boards over the decades, it was not until 2018 that considerable attention was devoted in best practice guidelines to the board's accountability to non-shareholder stakeholders. In its introduction, the *UK Corporate Governance Code* (FRC 2018) sets out that:

"successful and sustainable businesses underpin our economy and society by providing employment and creating prosperity. To succeed in the long-term, directors and the companies they lead need to build and maintain successful relationships with a wide range of stakeholders. These relationships will be successful and enduring if they are based on respect, trust and mutual benefit."

Principle A departs from the shareholder-centric approach taken in previous codes by outlining that the board is accountable to shareholders in a broader societal context; the board's role is described as being to promote the long-term sustainable success of the corporate, generating value for shareholders and contributing to wider society. Under Provision 5, the need for the board to understand the views of the corporate's key non-shareholder stakeholders is clarified. The board is encouraged to describe in the annual report how stakeholders interests have been considered in board discussions and decision-making. The board should keep engagement mechanisms under review so that they remain effective, particularly with respect to employees. Clarity in disclosure of remuneration arrangements is encouraged so as to promote effective engagement with shareholders and the workforce

(Provision 40). Such encouragement of accountability to the corporate's broader non-shareholder stakeholders is consistent with Section 172 of the UK Companies Act which sets out the duty of directors to promote the success of the corporate for the benefit of its members as a whole, with due regard to the interests of the corporate's employees; relationships with suppliers, customers, and others; and the impact of the corporate's operations on the community and the environment.

Summary

The progress made in encouraging board accountability within UK guidelines on best practice in corporate governance is evident. The standards expected of boards of directors of accountability to shareholders have continually increased. Yet, until recently, such guidance has been quite narrowly focused on financial accountability. Despite the setting out in legislation in 2006 of a director's duty to promote the interests of members of the corporate as a whole, including but not limited to employees, suppliers, customers, and society, a time period of 12 years elapsed before this is reflected in corporate governance guidelines. Accountability to broader stakeholders is acutely acknowledged as fundamental both to effective governance and sustainable corporate and economic development within the academic literature (McLaren 2004; Mason and Simmons 2014). From a traditional financial perspective, it is arguable that the shareholder-oriented approach to accountability taken over much of the past two decades may have positive externalities for more peripheral stakeholders in the corporate to the extent that directors' focus on maximizing shareholder wealth will enviably result in corporate growth, leading to job creation, productive relations with suppliers, and enhanced offerings to consumers (Mayer 1997; Roe 2000; Faleye et al. 2006). Yet, such focus may often entail efficiency measures which can have harmful impacts on working conditions, damage supplier relations, and even reduce the level of competition in the product

markets (Mayer 1997; Roe 2000; Deakin 2005; Goergen et al. 2014).

Early guidance on best practice in corporate governance might be considered to paradoxically lack focus on how board practices serve to enhance accountability, being largely concerned with structural aspects of the board. It was not until the *Higgs Review* in 2003 that significant guidance is offered on how board processes can support accountability. From a behavioral perspective of accountability, both relationships on the board and relationships between the board, shareholders, and other stakeholders are integral to ensuring responsibility is duly assumed and integrity underpins the corporate's business activities (Huse 2005). Since the financial crisis, UK guidelines on best practice in corporate governance have increasingly offered advice on how board behavior, processes, and relationships may contribute to greater accountability particularly with regard to risk-taking and ensuring the viability of the corporate in the long term. Similarly, the policy emphasis placed on how accountability in relationships along the investment chain, and between investment managers and directors, can help improve long-term returns to investors in the *UK Stewardship Code* may be seen as a necessary addition to the regulatory framework from the perspective of sustained accountability.

Notwithstanding such developments, scholars of corporate governance continue to note the lack of authentic evidence of accountability in the corporate setting (Harvey et al. 2019; Steckler and Clark 2019), noting that such heavy reliance on disclosure of accounting information does not necessarily lead to enhanced accountability or control (Du Rietz 2018). The self-regulatory governance framework followed in the UK may be considered too blunt an instrument to promote genuine accountability by corporate management to the range of stakeholders in the corporate (Harvey et al. 2019). Yet the ability of legally enforced rules to foster a true spirit of integrity and responsibility has long been questioned (Keenan 2004; Romano 2005; Arcot et al. 2010). Indeed, the self-regulatory approach in itself has its merits; the extent to which it is fit for the purpose of promoting accountability will inevitably depend on the

nature of issues arising between corporates, their shareholders, and other stakeholders. Often criticized for being somewhat reactionary in their construction, it has been pragmatically suggested that corporate governance policy which can sustain accountability ought to reflect not only the lessons learned from past crises and failures but to also account for changes which will impact regulatory models and practice in the long term (Brennan and Solomon 2008).

Accountability in Nonprofit Sector

Renato Civitillo

Department of Political Science (DISP),
University of Naples Federico II, Naples, Italy

Synonyms

CSR in nonprofit sector; Liability in nonprofit sector; Responsibility in nonprofit sector; Transparency in nonprofit sector

Definition

Accountability in nonprofit sector concerns an articulated assessment of global and overall consistency inherent in the following key elements:

- (a) Transparent use of financial and nonfinancial resources.
- (b) Correctness of management and governance.
- (c) Adequacy and conformity between actions and objectives.
- (d) Clear communication of the results achieved.

In essence, it is intended to refer to the application of the concept of accountability to the nonprofit sector. If the generic term accountability is very multifaceted, as it is highly debated and chameleon-like (Mulgan 2000; Messner 2009), it is even more complex and profound when referring to nonprofit institutions (NPIs) (Rademacher and Remus 2017). In fact, it presents an evident versatility, being able to represent a principle, a duty, a system, a process, a mechanism, a set of tools and techniques (Ricci 2019): it describes the need to report, responsibly, the work of NPIs towards all stakeholders regarding the use of the resources, the correctness of the management, the correspondence and the consistency of the activities with respect to the programmed objectives (Ricci 2016). The final aim is to allow the correct demonstration of social value (Campbell 2002) and public value (Moore 1995; Esposito and Ricci 2015) generated by NPIs, which are necessary to guarantee their success (Krisch and Grabner-Kräuter 2017).

Introduction

As argued by literature, a fundamental aspect of the management of any economic institution is represented by the processes involved in evaluating performance (Speckbacher 2003). Nonetheless, it must be stressed that this statement, although valid from a theoretical-general point of view, cannot be abstractly referred to any type of organization, and with the same modalities of application.

In this perspective, the nonprofit sector constitutes a very particular area of economic organizations characterized by three peculiarities (Anheier 2000; Civitillo 2016):

- 1. The absence of the profit purpose.
- 2. The difficulty of using reliable financial parameters and criteria.
- 3. The mission is strongly influenced by the set of values pursued with its activities.

These elements give to NPIs characteristics of hybridity which make it very difficult to identify models, principles, criteria and tools useful for the correct management of these economic organizations.

Furthermore, since NPIs do not find their main management driver in profit, a further consequence is that performance assessment in these particular entities is extremely ambiguous, mainly due to their value system which is vast, unclear, vague, imprecise, heterogeneous and difficult to express with measures.

It is clear that the value system of NPIs (e.g., politics, religion, health, environment, ethics, morals, voluntarism, philanthropy, compassion, etc.) affects the set of programmed objectives and the ways in which these are achieved (Najam 1996; Porter and Kramer 1999; Moore 2000; Putnam 2001; Speckbacher 2003; Toepler and Anheier 2004).

This means that in NPIs the connection between their organization and their value system is so close that the mission takes an enormous importance, also in relation to the organization and management of these institutions (Moore 2000; Smith 2008). In this sense, the mission of NPIs can be useful to define the value system to which NPIs are intended (Moore 2000).

Many theories have tried to correctly interpret the existence of NPIs, most of which are relatively recent (DiMaggio and Anheier 1990; Hansmann 1996; Rose-Ackerman 1996; Salamon and Sokolowski 2004). In essence, they seem to pose a crucial question: whether market economies are aimed at profit, why are there some organizations that decide not to foresee profit as a priority of their system of values?

To answer this question, a very useful starting point could be the identification of the main characteristics of NPIs (Salamon and Anheier 1996; Anheier 2014).

In this sense, it is very interesting to highlight that NPIs could (or probably should) be more correctly considered as “nonprofit-distributing” organizations rather than as “nonprofit-making” entities (Anheier 2014), mainly because NPIs are structurally conceived as economic organizations in which the incoming monetary flows are destined to the exercise of their institutional activities and, therefore, to their mission; on the contrary, it is not foreseen that incoming resources can be distributed, in any way, to the different governing bodies of the same organizations.

All this means that any financial resources generated by the action of this particular type of organization are mainly reinvested or, in any case, destined for the declared mission of it.

This first argument would lead to the following conclusions:

- (a) NPIs, unlike private companies, are extraneous to the generation of profits or, in general, of positive financial results.
- (b) The acquisition of resources (financial and nonfinancial) in NPIs is very sensitive to levels of efficiency and effectiveness in the pursuit of the aforementioned institutional needs, with obvious management consequences.

The second statement is particularly useful to highlight that the management of NPIs can never allow the abandonment of the basic economic paradigms typical of any economic organization, regardless of whether it is of the “profit” or “nonprofit” type. In both cases, managerial processes and patterns are substantially similar, to diverge only for aspects related to the specific purposes: “profit” or “nonprofit” goals (Civitillo 2016).

Accountability in Nonprofit Institutions

In the context just described, a very important concept is represented by profit, which can be conceived as a sort of fuzzy and multiform concept: if it is indisputable that it cannot be assumed as a possible absolute indicator of the capacity to create value of any type of economic

organization (Ricci and Civitillo 2019), this is particularly true for NPIs which are not institutionally prearranged for profit (Moore 2000; Dees 2001).

In this sense, the real and concrete value attributable to NPIs could be identified in the construction of social relations with communities and citizens of a certain territory (Porter and Kramer 1999; Putnam 2001; Tenbensen et al. 2014): in some fields, nonprofit sector is able to generate indisputable advantages in terms of social value production, such as the creation of networks to exchange information from/to the communities or social and professional networking (Porter and Kramer 1999; Wondolleck and Yaffee 2000; Smith 2008).

However, it should be noted that nonprofit sector and its institutions have also been subject to a complex process of importing business-type methodologies and tools, similarly to what happened for the Public Administration with the typical approaches of New Public Management. This has led to a progressive loss of their civic-engagement characteristic, resulting in a decrease in their degree of representativeness and democracy (Smith 2010; Skocpol 2013).

All this has meant that NPIs, up to now, have been considered as organizational entities whose objective of optimizing and maximizing performance levels do not appear compatible with the pursuit of the civic-engagement objectives that characterize their value system.

In truth, however, it is possible to identify a sort of complementary element to the performance objectives: it is the accountability concept which, in this perspective, does not represent an obstacle to the performance objectives of NPIs but, on the contrary, a process that is able to improve the overall management of these organizations (Boris and Steuerle 2006; Ricci and Civitillo 2017, 2018). NPIs increasingly emphasize the notions of performance measurement and accountability as the same assessment of the organization’s ability to properly fulfill its mission is effective only in the presence of an efficient information level of performance. On the other hand, the absence or even the limitedness of information lead to inevitable unfortunate consequences, as

well as a series of negative externalities such as the reduction of the level of public trust in NPIs which, obviously, can seriously compromise the same survival of these organizations, as well as their development (Speckbacher 2003).

It is therefore evident that, in this context, accountability plays a fundamental role (Dubnick 2011), as it implies the duty to act in a responsible way and to be accountable to others for one's actions, in order to maintain effective and logical links between planning, deciding, action, and verification (Ricci 2016). Although accountability represents "a complex and chameleon-like term" (Mulgan 2000, p. 555), recently, it has significantly expanded its relevance, becoming a fundamental factor for various aspects of citizens' lives.

According to Mulgan (2000), accountability can take on at least four meanings:

1. Accountability as a sense of responsibility for the public interest expected of public employees (professional and personal accountability).
2. Accountability as a democratic control system of government actions (accountability as control).
3. Accountability as a criterion for pursuing the desires or needs of communities (accountability as responsiveness).
4. Accountability as a form of public dialogue for citizens (accountability as dialogue).

All this implies that accountability, with specific reference to NPIs, refers to the need to make the use of financial and nonfinancial resources transparent, but also about the correctness of the management capacity, the adequacy and conformity between actions and objectives, and the clear reporting of results achieved by the organization (Rosenfield 1974; Behn 2001). This determines that clear representation of policies and rules relating to the political, social, cultural context in which NPIs operate appears today a fundamental requirement to guarantee the achievement of their planned objectives and, therefore, their success. Consequently, despite a physiological reciprocal link, performance measurement and

accountability remain different, especially regarding the objectives pursued: accountability necessarily implies the complete, systematic and transparent reporting of the multifaceted organizational structure of an economic organization, both financial and (or, perhaps, above all) non-financial nature (Civitillo 2016). In this sense, for example, accountability may be able to demonstrate the efficient and effective use of money in the organization and the level of goods and services produced. It is only in this way that the user is able to know the public value generated (Moore 1995; Esposito and Ricci 2015).

In this context, NPIs are able to generate high level of social value goods and services (Campbell 2002) which, very often, are not actually supplied either by Market or by Public Administrations since they do not fall within their respective productive or strategic advantages: consequently, accountability can be the ideal tool also to increase the visibility of these organizations, which is a particularly relevant aspect (Krisch and Grabner-Kräuter 2017).

Notwithstanding the scientific literature shows how the studies have always focused almost exclusively in relation to the for-profit institutions (Habisch et al. 2005; Barth and Wolff 2009; Idowu et al. 2015), it is essential to point out that accountability is a prerequisite for NPIs because it allows them to demonstrate to the stakeholders the effective ability of the organization to pursue the objectives set by its mission (Nardo and Siboni 2018).

In the current era, the objectives of NPIs include a far too wide range of activities, such as education, healthcare, charity, religion or culture, just to give a few examples: these are activities intimately connected to citizens and, in general, to the civilian community and which, above all, presuppose a high degree of confidence and trust.

As a result, anything that is capable of harming this trust relationship – even if only potentially – may have enormous repercussions on the financial resources of NPIs.

This means that today, maintaining an adequate level of trust in the nonprofit sector is no longer a mere alternative of growth development but rather:

- A real need, in order to improve the management of NPIs.
- A moral or ethical duty or obligation, in consideration of the institutional goals of the organizations in this sector.

What has just been highlighted assumes even greater importance in consideration of the development of the SDGs and the 2030 Agenda for Sustainable Development by the United Nations which, in fact, have made the role of the Nonprofit sector even more relevant for the pursuit of the general objective of sustainability of the global economy:

“All countries and all stakeholders, acting in collaborative partnership, will implement this plan. We are resolved to free the human race from the tyranny of poverty and want and to heal and secure our planet. We are determined to take the bold and transformative steps which are urgently needed to shift the world on to a sustainable and resilient path. As we embark on this collective journey, we pledge that no one will be left behind” (United Nations 2015, p. 3).

Following the program envisaged by the SDGs, all the actors of civil society are called to contribute to reach a concept of sustainability:

- Authentic, trying to overcome the traditional notion of development through the broader concept of prosperity.
- Multifaceted, as it includes the multitude of social actors and the numerous aspects of sustainability such as efficiency, responsiveness, innovation, etc.
- Dynamic, as it should not be a static conceptual goal, but rather a dynamic balance, able to absorb and react to the different changes in the external environmental context.

Summary

Accountability in nonprofit sector concerns an articulated assessment of global and overall consistency inherent numerous key elements such as: transparency, correctness, adequacy, conformity, coherence and communication about nonprofit institutions (NPIs).

Nonprofit sector constitutes a very particular area of economic organizations characterized by some peculiarities which attribute to NPIs characteristics of hybridity and make it very difficult to identify models, principles, criteria and tools useful for the correct management of these economic organizations.

It is clear that the value system of NPIs (e.g., politics, religion, health, environment, ethics, morals, voluntarism, philanthropy, compassion, etc.) affects the set of programmed objectives and the ways in which these are achieved (Najam 1996; Porter and Kramer 1999; Moore 2000; Putnam 2001; Speckbacher 2003; Toepler and Anheier 2004).

In this perspective, accountability represents the duty to report, responsibly, the work of NPIs towards all stakeholders regarding the use of the resources, the correctness of the management, the correspondence and the consistency of the activities with respect to the programmed objectives (Ricci 2016). The final aim is to allow the correct demonstration of social value (Campbell 2002) and public value (Moore 1995; Esposito and Ricci 2015) generated by NPIs.

[Accounting for the carbon; GHG accounting](#)

Definition

Mounting social and legal concerns worldwide about rapid increase in Earth's average global surface temperature and resultant climate change have led to building mechanisms such as the Kyoto Protocol for reducing GHG emissions. The Kyoto Protocol is an international treaty under United Nations Framework Convention on Climate Change (UNFCCC) where the signatory parties commit to reduce GHG emissions as per

the defined emission reduction targets (UNFCCC 2020a). The implementation of the Protocol and resulting carbon trading have given rise to the need for accounting GHG-related information of an entity. Accounting for GHG emissions or simply GHG accounting is the process by which an entity monitors, measures, and accounts for the emission of carbon and other major GHGs as defined under the Kyoto Protocol. GHG emissions can be accounted and reported at global, national, regional, corporate, product, or project levels within or outside the Protocol. GHG accounting helps an entity in predicting and measuring its carbon footprint and in understanding the costs and benefits associated with carbon-related actions. It provides concerned stakeholders with factual information for GHG-related decision-making.

Introduction

In the past few decades, unprecedented increase in GHG emissions, global warming, and the resultant climate change have become some of the most pertinent global challenges. "Warming of the climate system is unequivocal, as is now evident from observations of increases in global average air and ocean temperatures, widespread melting of snow and ice and rising global average sea level" (IPCC 2007). The first major international step in the direction of dealing with this situation was the United Nations Framework Convention on Climate Change (UNFCCC). The Convention was first held in 1992 where it was agreed by most of the participating countries that there is an urgent need to control GHG emissions so as to reduce the heat on the Earth and the resulting climate-related problems. In December 1997, the third session of the Conference of Parties (COPs) to the Convention was held in Kyoto, Japan, where the Kyoto Protocol was adopted aiming at concerted international efforts to reduce global GHG emissions. The Kyoto Protocol became legally binding in 2005. The Protocol covers six main GHGs which are given in Annexure A of the Protocol. These include "carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O),

hydrofluorocarbons (HFCs), perfluorocarbons (PFCs) and sulphur hexafluoride (SF₆)” (United Nations 1998). Each of these gases has a different global warming potential (a capacity to heat the atmosphere), so these are converted into equivalent tons of CO₂, the most important GHG and the one that represents the vast majority of the world’s GHG emissions (about 55%). “Carbon dioxide is the most important anthropogenic greenhouse gas. The global concentration of carbon dioxide has increased from a pre-industrial value of about 280 ppm to 379 ppm³ in 2005” (IPCC 2007). Because of this, GHG accounting is also sometimes referred to as carbon accounting.

The Kyoto Protocol divides participating countries into two groups: Annex I (Developed) countries and Non-Annex I (Developing) countries. It was recognized that developed nations are mainly responsible for the current levels of GHG emissions in the atmosphere. Hence, the Kyoto Protocol assigned the binding responsibility for reducing emissions only to the developed nations under the principle of “common but differentiated responsibility and respective capabilities” (UNFCCC 2020b). The developing countries were not given any binding targets. The first commitment period for the Kyoto Protocol was from 2008 to 2012. The target for the first commitment period was to reduce the combined GHG emissions by 5% of the 1990 levels (United Nations 1998). In 2012, the Doha Amendment was adopted where new commitment period starting from 2013 to 2020 was agreed and a revised list of GHGs was decided (UNFCCC 2020c). In order to enable Annex I countries to meet their emission reduction targets in a cost-effective manner, the Protocol prescribed three mechanisms, namely, Clean Development Mechanism (CDM), Joint Implementation (JI), and International Emission Trading (IET) (UNFCCC 2010). The implementation of these mechanisms led to the creation of a new commodity in the form of emission reduction or removal units which is traded in the carbon markets, each unit representing one ton of CO₂ removed from the atmosphere or saved from being emitted (UNFCCC 2020d).

The Kyoto Protocol and the related carbon trading gave rise to the need for accounting GHG emissions and preparing GHG inventories.

Accounting for GHG emissions involves identifying GHG emission sources, measuring GHG emissions of an entity, preparing GHG inventories, finding carbon footprint of a concern, verification of GHG accounts, and reporting GHG-related information to the concerned stakeholders. GHG inventories include all emissions and removals of GHGs from a given entity during a specified period of time. GHG accounts/statements are prepared using internationally recognized data collection methods suggested under the Kyoto Protocol, GHG Protocol, or other recognized standards.

Accounting for GHG Inventories

In order to collect and report credible and reliable information on GHG emissions of any entity, GHG inventories are prepared. “GHG inventories are estimates of all emissions and removals of greenhouse gases (GHG) from given sources or sinks from a defined region in a specific period of time” (IPCC 2015). Such inventories can be prepared at global, national, regional, corporate, product, or project levels. GHG inventory information is required by policy makers to formulate, implement, and enforce policies related to reduction in GHGs.

There are standard reporting requirements for preparing national GHG inventories by parties to the Kyoto Protocol. In order to ensure quality, integrity, and completeness of national GHG inventories, “the UNFCCC reporting guidelines on annual inventories for Annex I Parties require use of the 2006 IPCC Guidelines for National Greenhouse Gas Inventories” (UNFCCC 2020e). National inventories record all anthropogenic emissions and removals. “Anthropogenic emissions and removal means that greenhouse gas emissions and removals included in national inventories are a result of human activities” (IPCC 2006). The Kyoto Protocol specifies the rules for determining about the sources and sinks which are to be considered while calculating permitted emissions of a country (Ratnatunga 2007). GHG inventories at state, city, or regional levels can also be made using a similar approach. The national GHG inventory data for Annex I countries is published by UNFCCC (UNFCCC 2020f).

For quantifying and recording GHG emissions at corporate, project, or activity levels, business organizations all over the world use GHG protocol. “GHG protocol establishes comprehensive global standardized frameworks to measure and manage GHG emissions from private and public sector operations, value chains and mitigation actions” (GHG Protocol 2020a). The GHG protocol divides emission sources into three categories (GHG Protocol 2011):

- Scope 1 – Direct emissions from sources owned or controlled by a business
- Scope 2 – Indirect emissions from purchased or acquired electricity, steam, heat, and cooling
- Scope 3 – Indirect emissions that occur from sources not owned and controlled by the concern. These may be caused by a concern’s value chain – upstream or downstream activities. It may represent largest source of emissions for companies.

Corporate GHG inventories include all GHG emissions (direct as well as indirect) caused by a concern. The protocol’s corporate accounting and reporting standard provides guidance for quantification and reporting of corporate-level GHG emissions (GHG Protocol 2020b). The aim is to help concerns in preparing GHG inventories using standard techniques and principles. It not only simplifies the procedure of compiling GHG inventories but also increases credibility, consistency, and transparency of the reported GHG information. The corporate standard can also be used by nonprofit-making organizations like NGOs, educational institutions, or government offices. In 2015, the corporate standard was revised to provide more guidance on measurement and reporting of Scope 2 emissions (GHG Protocol 2020b). The corporate value chain (Scope 3) standard allows a company to measure the emission impact of its entire value chain and helps in knowing where the reduction is possible (GHG Protocol 2011).

For calculating GHG emissions from specific emission reduction/mitigation projects, project-level GHG protocol is used. “The GHG Protocol for project accounting provides principles,

concepts and methods for quantifying and reporting GHG reductions- i.e. the decreases in GHG emissions, or increases in removals and/or storage- from climate change mitigation projects” (GHG protocol 2005). The aim of project-level accounting guidance is to provide credible and reliable information on GHG reductions from GHG mitigation projects. Other standards issued by GHG protocol include standard for cities. Mitigation goal standard, policy and action standard, product standard, and project standard (GHG Protocol 2020c). “GHG protocol tools enable companies and cities to develop comprehensive and reliable inventories of their GHG emissions, and help countries and cities track progress toward their climate goals” (GHG Protocol 2020d).

The International Organization for Standardization (ISO) has also issued several standards on GHG accounting. Important among these are ISO 14064-1, ISO 14064-2, and ISO 14067. “While ISO 14064-1:2018 deals with quantification and reporting of GHG emissions and removals at organization level; ISO 14064-2:2019 provides guidance on quantification, monitoring and reporting of GHG emission reductions or removal enhancement at project level” (ISO 2020). In order to harmonize GHG accounting during project appraisals, International Financial Institutions (IFIs) use GHG accounts of a project which are prepared using established calculation approaches and methodologies “provided by GHG protocol, CDM methodology, verified carbon standards, gold standard and EU emission trading schemes, ISO 14064 (1) and (2) and other international standards” (UNFCCC 2015, 2019).

Life Cycle Accounting (LCA)

At the product level, life cycle technique is used these days to track emissions associated with a specific product or service throughout its life. This is also known as life cycle accounting (LCA). “Life-cycle greenhouse gas (GHG) accounting evaluates and reports the full life-cycle GHG emissions associated with the raw materials extraction, manufacturing or processing, transportation, use, and end-of-life management of a good or service” (EPA 2019a). ISO 14067: 2018 also

deals with GHG gases – carbon footprint at product level (ISO 2020).

Carbon footprint can also be calculated at home level. GHG emissions caused by day-to-day activities like use of electricity in home appliances, gas leaks from refrigerators and air conditioners, driving of cars or waste disposal, etc. together make up a household's carbon footprint. "EPA carbon footprint calculator helps to estimate carbon footprint in the areas of home energy, transportation and waste" (EPA 2019b).

Verification of GHG Accounts

In order to reduce risk of inaccurate disclosure of GHG emissions and other GHG-related information in the reports published by an entity, an independent external assurance of GHG inventories is required. "ISO 14064-3 is an internationally recognized standard for verification and validation of GHG assertions" (ISO 2020). The standard is applicable for organization-, project-, and product-level GHG statements. It is designed to be flexible and program neutral, so it can be referenced or used in multiple voluntary or regulatory regimes (Weng and Boehmer 2006). The International Auditing and Assurance Standards Board (IAASB) has also released International Standard on Assurance Engagements (ISAE) 3410 on Assurance engagements on GHG statements in 2012 (IAASB 2012). To ensure accuracy, completeness, consistency, and comparability of national GHG inventories, IPCC validation and verification guidelines are used (IPCC n.d.). The UNFCCC suggests the use of principles of accuracy, comparability, completeness, consistency, and transparency to guide the development of national GHG inventories. Same principles can be modified for other types of GHG accounting. These accounting principles provide guidance to practitioners in GHG accounting as well as to those verifying these accounts.

Benefits of GHG Accounting

The main objective of GHG accounting is to provide accurate, reliable, and comparable GHG

emission information to the policy makers so as to assist them in making strategies to combat climate change. GHG accounting helps in identifying opportunities to reduce GHG emissions, controlling GHG-related risks, improving emission management system, and achieving GHG reduction targets (Tang and Luo 2014). GHG statements prepared by an entity also provide information on the avoided GHG emissions, i.e., the amount of CO₂ and CO₂ equivalents that has not been or will not be released into the atmosphere as a result of various steps undertaken like tree plantations, use of renewable energy, pollution control measures, etc. It helps in building efficient emission reduction policies in the future by setting measurable and more ambitious emission reduction goals and tracking progress of emission reduction projects efficiently and comprehensively. GHG accounting is also needed to understand costs and benefits associated with GHG mitigation strategies. Quantification of the benefits of such mitigation projects encourages business organizations to come up with more innovative ideas to reduce GHG emissions. "Countries and individuals can do a better job addressing climate change when they understand the true sources of their emissions, whether generated at home or in the manufacturing and shipping of products from around the globe" (UNFCCC 2015b). Accurate measurement of GHG-related data and reporting of externally verified carbon statements to various internal and external stakeholders help them in making informed decisions.

Summary

In the past few decades, the role of GHG accounting in managing an entity's GHG emission-related data has gained significant importance. GHG accounting is the process of measuring, recording, analyzing, and reporting information on carbon dioxide and other GHGs emitted by an entity over a period of time. The emissions are measured in a standard unit, i.e., tons of carbon dioxide equivalents. GHG inventories can be prepared at various levels using internationally recognized

quantification and reporting methods. GHG accounting helps entities to understand their carbon footprint and related climate change impacts. Preparing credible and reliable GHG accounts helps in managing GHG-related risks, identifying GHG reduction opportunities, meeting GHG reduction commitments, reporting reliable data to concerned stakeholders, and participating in the carbon markets.

Description

Acid rain is one of the effects that Air Pollution (see) has on our planet, along with global warming and the ozone hole. They involve the fallout to the ground of acid substances (precipitation, particulate matter, aerosols, and gas). What is commonly known as “acid rain” should be more correctly defined as “acid deposition” or “acid precipitation.”

This issue can be distinguished in “wet deposition” (rain, snow, sleet, hail, fog, or dew) and “dry deposition” (dust or other acidifying micro-particles, smoke, gases, or aerosols) not conveyed to the ground by precipitation, but by physical mechanisms and times that depend mainly by gravity and the characteristics of microparticles (size and weight).

In the particular case in which the particles of pollutants are wrapped inside the drops of fog or clouds and reach vegetation in this physical state, some authors call this phenomenon not “wet deposition” but “occult deposition.”

Introduction

Dry depositions, in general, occur near the regions from which the emissions originate and within a few days. Wet depositions, on the other hand, are not just a local phenomenon, confined exclusively within densely industrialized areas, but global. In fact, due to the wind and to the widespread use of tall chimneys, they fall to the ground far from the

emission places, on very distant territories that are considerably large and after a long time, thus assuming a transnational (sometimes, also intercontinental) connotation and gravity (Haradhan 2018). It is therefore indispensable to study also the role and the dynamics of atmospheric currents to monitor the movements of polluting chemical forerunners (or precursors of acid rain) from their origin to precipitation.

The eastern regions of the United States and Canada and northeastern Europe (from Poland to Scandinavia) have been affected by acid rain since the 1980s, when some studies estimated that half of the trees in the Black Forest had suffered damage (UN 2019).

The first to notice and describe the negative effects of air pollution on Arundel marbles (Oxford) was the English writer John Evelyn in 1661 in his book *Fumifugium*. While the first to coin the term “acid rain” (in French “pluie acid”) was in 1845 the pharmacist M. Ducros (Menz and Seip 2004).

A few years later, in 1852, the Scottish chemist Robert Angus Smith – in his detailed and pioneering studies, reported later in 1872 in his book “Air and Rain: The Beginnings of a Chemical Climatology” – used the same term to describe the potentially harmful effects of the atmospheric polluting phenomenon deriving from the massive use of high-sulfur coal in Manchester and in other northern British cities (Gorham 1982).

The first alarming research on this issue, on large-scale was conducted in the countries of the Scandinavian peninsula by some scholars. Among them, the Norwegian geologist and mineralogist Waldemar Christopher Brøgger, in a note in “Naturen” (1881), and the Swedish soil scientist and chemist Svante N.F. Oden (1976) established, without uncertainty, that the increase in acidification of surface waters of Norway and Sweden was to be attributed to the long-distance transport of atmospheric pollutants from United Kingdom and central Europe. Since then, research on the monitoring of pollutants, their transnational movements, and receptor sites has increased along with a growing public concern about the possible risks to ecosystems.

Causes

The formation of acid rain is essentially attributable to the presence in the atmosphere of different pollutants or acid precursors: carbon dioxide (CO_2), sulfur oxides or SO_x (mainly SO_2), and, to a lesser extent, nitrogen oxides or NO_x (NO and NO_2).

The presence of these substances may be due to natural phenomena, such as: volcanic eruptions, lightning, wildfires, bacterial degradation of organic substances, and the respiration processes of plants and animals. However, human activities are mainly responsible for the release of pollutants because they massively burn fossil fuels (coal, oil, and natural gas).

In fact, in addition to releasing SO_2 and NO_x during their combustion, coal and fossil hydrocarbons also contain small amounts of sulfur which, burning and reacting with air oxygen, produces SO_2 . The main natural biological source of sulfur compounds is dimethyl sulfide (DMS) released into the atmosphere primarily from the oceans (Brimblecombe 1994).

Nitrogen oxides, on the other hand, are produced by the high temperatures of combustion processes and lightning; the high heat, in fact, breaks the strong bonds of the diatomic molecule (N_2) and causes the combination of nitrogen with oxygen.

Atmospheric CO_2 , on the other hand, derives not only from volcanic eruptions and from the combustion of any substance, but also, as known, from the respiration processes of plants and animals.

The main anthropogenic sources of SO_2 are industrial sites (manufacturing, oil refineries, and other industries), domestic heating systems, thermoelectric power plants, etc., which use coal and petroleum fractions containing small amounts of sulfur; while the main sources of NO_x are motor vehicles, characterized by high operating temperatures.

With water (both in the liquid state and in atmospheric vapor) or with the hydroxyl radical $\text{OH}^\cdot$, the precursors are transformed into airborne weak and strong acid substances, for the most part, already before their deposition: carbonic

acid (H_2CO_3 ; ionizing in water as HCO_3^-), sulfuric acid (H_2SO_4 ; SO_4^{2-} in water), and nitric acid (HNO_3 ; NO_3^- in water). Dry depositions, on the other hand, cause the formation of acids only after they have been deposited on the Earth's surface soil (Irwin and Williams 1988).

Recently, following the circumstance that, in many regions, both the emissions of sulfur oxides and of nitrogen have declined, ammonia (NH_3) emissions (from fertilizers, animal, and natural sources) and ammonium (NH_4^+) depositions have received widely increased attention as contributors to ecosystem acidification (Burns et al. 2016).

Effects

The effects of acid rain are considerable not only for Biodiversity (see) and the persistence of ecosystems, but also for buildings and for human health itself. In fact, they cause acidification of surface freshwaters (lakes and streams), damage soil, forests, flora and fauna in general (mainly at high altitude where rainfall is more abundant). The damages of acidity are very evident not only to the plants (terrestrial and aquatic) – heavily affecting their growth and reproductive capacities – but also to the animals, and in particular to the aquatic ones.

For flora, the phytotoxicity of acid deposition, even for evergreen trees, result either from the direct absorption of these acids through the gaseous and liquid exchanges by roots and leaves (whose protective wax coating is attacked and damaged by acid solutions, so interfering with photosynthesis) (Huttunen 1994) or, indirectly, from the variation of the organic and inorganic components of the soil (humus and minerals). All this increases the vulnerability of plants to climatic stress and to pest attacks.

Acid depositions, in fact, by lowering the pH of a soil and modifying its chemical composition (mineralization of organic matter, fixation of nitrogen, etc.) cause the progressive disappearance of the edaphon (bacteria, fungi, algae, protozoa, rotifers, etc.) – that is of those organisms that live in the soil and that have fundamental

importance for plants (many of these microorganisms are saprophytes or symbionts) also because they decompose organic substances – and the reduction of the presence of basic cations: e.g., calcium (Ca), magnesium (Mg), potassium (K), and phosphorus (P) (Fischer et al. 1996).

The fauna of lake and streams is damaged both by the higher acidity of the environment in which it lives and by the presence of some toxic substances (i.e., inorganic monomeric aluminum) released by a decrease of pH. Freshwater basins (lakes, streams, and wetlands) generally hold onto fragile and delicate ecosystems, so that the disappearance of a plant or animal species, which is more sensitive to an increase in acidity, causes a series of repercussions, not very predictable and controllable, on the other species living in the same environment.

The most rapidly affected aquatic animals are shelled organisms, like crustaceans (mainly shrimps) and mollusks (mussels and snails), and the most sensitive insects, interfering with egg hatching and the embryonic growth. With further acidification, plankton, small fish (i.e., minnows), and frogs begin to be lost and, subsequently, the increasingly bigger ones – and, even, nonaquatic species, such as birds – which are positioned at the top of the food chain of that specific ecosystem (Tagliarolo 2019).

The magnitude of these effects and the acidity neutralization also depend by other factors according to source-receptor relationships: characteristics of the basin itself (e.g., number influents and effluents, water turnover rate, presence of underground springs, etc.); the “buffering capacity” (presence of chemical complexes that can accept or donate hydrogen ions); the alkalinity or the acid-neutralizing capacity (ANC, measuring the amount of strong base in a solution) of the receptor (Jenkins et al. 2005).

The direct negative effects of acid rain on human health – i.e., by skin contact with contaminated water – can be considered almost nonexistent. Only inhalation of irritating substances from dry depositions can cause respiratory diseases: irritations of the respiratory tract, asthma, and other respiratory pathologies. Much more serious, on the other hand, are the indirect effects

(respiratory, cardio-circulatory, and also tumoral pathologies) of wet depositions that can arise from the ingestion of water and foods (vegetables or animals), in which toxic bioaccumulative substances (heavy metals such as aluminum, zinc, cadmium, lead, and mercury) made bioavailable, in a toxic form, by acid in soil or in basins (Norton et al. 2014).

Moreover, visibility undergoes significant deterioration through the absorption and reflection phenomena of light due to the presence of acid precursors in the air.

Acid rain also causes considerable damage to the materials (limestone, marble, reinforced concrete, iron, copper, bronze, etc.) of which man constructions (monuments, buildings, bridges, and other buildings) are constituted, accelerating their corrosion and decay. In particular, calcareous stones, attacked by sulfuric acid, are transformed from calcium carbonate (CaCO_3) into calcium sulfate or gypsum ($\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$), much more porous, fragile, and easily damaged by rain and wind with significant repercussions on the historical and cultural heritage and on the economy of a nation.

Remedies

For several decades until now, developed countries have established discussion tables to find shared and global solutions to this problem and to others connected to it, such as the Greenhouse Effect (see) and Global Warming (see). Among the most important international treaties in this regard are the Geneva UN Convention of 1979, on the control of transboundary air pollution, and the 1997 Kyoto Protocol (see), in which the idea of the Emissions Trading System (ETS) was conceived.

In the United States in particular, over the years, a number of programs and networks have been launched, organized by the Environmental Protection Agency (EPA) as leader, for continuous and long-term monitoring of precipitation chemistry and acid deposition, both in wet that dry state: the National Atmospheric Deposition Program (NADP) since 1978; the National Acid

Precipitation Assessment Program (NAPAP), established by the US Congress in 1982 to incorporate the NADP network into the National Trends Network (NTN); The Long-Term Monitoring (LTM) project, implemented in 1983, controlling the acidity levels of about 180 lakes and streams; the Clean Air Status and Trends Network (CASTNET), established under the 1990 Clean Air Act Amendments; the 1990s Environmental Monitoring and Assessment Program (EMAP), a long-term umbrella program for the US EPA that includes the LTM and the TIME (Temporally Integrated Monitoring and Ecosystems) projects.

The most immediate and most effective remedy would be to implement policies and strategies, for individuals or entire nations, that require less use of fossil fuels. In particular, a greater use of renewable energy sources (solar and wind power, first and foremost) and a greater diffusion of electric cars could greatly help to achieve this goal.

In combustion processes, effective technological solutions (before, during, and post combustion) are already implemented to reduce the formation of sulfur and nitrogen oxides: removing sulfur and its compounds from fuels through desulfurization processes or using low sulfur-based fuels; optimizing the stoichiometric air-fuel reactions and lowering the combustion temperatures so as to reduce the formation of NO_x ; reducing NO_x catalytically and desulfurizing the combustion fumes, by Flue-Gas Desulfurization (FGD) technologies.

For strongly acid limited areas of land and small basins of fresh water, the spreading of basic buffer substances (liming) or strong base cations (SBC, i.e., powdered limestone, CaCO_3) could be implemented. These operations, however, are to be considered only a limited and immediate solution both because their effects are only temporary and because they are very expensive. Similar projects have been carried out for the lakes and streams of Sweden, Norway, and Wales (Lawrence et al. 2016).

Other possible solutions can be found in: the modernization of the existing thermoelectric park (through the gradual replacement of the old coal-fired power plants with more efficient ones, such

as those with combined cycle gas turbine or CCGT); a greater use of public transport; regulating the vehicles emissions and lowering speed limits; and, in general, raising public awareness to implement more environmentally friendly lifestyles.

Summary and Conclusion

The problem of acid depositions of man-made origin exploded with the First Industrial Revolution (second half of the eighteenth century), following the increasing use of fossil fuels. Since then, this issue has continued to worsen, also due to population growth. In recent years, countries with the most advanced economies have reduced their emissions, especially of sulfur oxides, while this has not happened for nitrogen oxides. For developing countries and for those nations with high industrial growth (i.e., those of Asian region), pollutants emissions continue to grow and generate acid depositions.

Action Research

Chahid E. Fourali

London Metropolitan University, London, UK

Definition

Action research is a form of enquiry that integrates theory and action to address real life problems. It enables practitioners to systematically evaluate and improve their practice. The number of types of action researches has multiplied over the last 50 years (Fourali 2016) or so and, accordingly, so did the number of definitions offered. These usually refer to the following characteristics of AR:

1. Use of an iterative model (e.g., Kolb's model) for systematically analyzing, testing, and reviewing the reality being faced
2. Involve the participation of stakeholders with a purpose of co-design of solution
3. Support in depth analysis of faced situation that goes beyond addressing the symptoms
4. May refer to several disciplines to help understand and address the faced problems
5. Is inclusive and ethically informed

Various authors were identified as the originators of action-led research and learning. These included Kurt Lewin, Reg Revans, and Kolb. Fourali argued that the approach has been used by some authors more than others its steps are akin to what might be labeled a problem-solving perspective which may not only apply to education but all scientific enterprises facing practical problems. Accordingly, all civilizations who developed solutions to practical problems may be seen to have contributed to the action research methodology.

Introduction

Action research has been developed to remind us that all practitioners (initially, in education,

but later, in any discipline) can develop their professional expertise through undertaking action research to any problematic situation they may face and that may involve one or a multitude of cases. Also practitioner-researchers may not be restricted by the circumstances of the “accepted ideologies” of received research reports. Hence, AR is an empowering method that does not simply encourage practitioners to wait for the research undertaken by the experts but, rather, encourage them to seek their own solutions that may be particularly suited to the unique situation they may be facing. Such benefits were particularly demonstrated by practitioner researchers such as Paolo Freire (1970).

As stated above, there are a number of iterative steps that have been developed to guide action researchers. One model stipulates the following steps: Diagnosing, Action planning, Taking action, Evaluating, and Specifying learning. Another simply suggests four steps: Reflecting, Planning, Acting, and Observing. Recently, Fourali (2016) suggested that since all steps require “reflection” they should be reflected with the model as follows:

Steps of action research (Fourali 2016)

Key Issues

As stated above, action research is seen as a family of approaches rather than one particular technique. Some classify it as “qualitative approach” while others classify it as a mixed design approach to the problem addressed. The later view seems to be closer to the reality since a researcher may combine both quantitative and qualitative (say bottom up approach) to understand and find a way forward for the addressed problem. At the moment one might argue that five versions of AR have been particularly used. These include (McNiff and Whitehead 2011; Coghlan and Brannick 2005):

Action science: This approach differentiates the researchers formally adopted theories and their individual theories of action.

Cooperative/collaborative enquiry: This approach advocates going through four stages of “propositional knowing,” researcher’s “practical knowing,” externally verified “experiential knowing,” and “creating new knowledge and ways of acting.” If the last stage is unsatisfactory then another iteration through the four stages is advised.

Participatory AR: Although this approach was initially associated the critical pedagogy movement promoted by Paulo Freire, it has developed multiple perspectives with the dual aims of knowledge making and social change. It accounts the present by referring to historical factors and aims to establish a more just society through promoting a more inclusive democratic perspective.

Developmental action research enquiry: This is perhaps one of the most challenging versions of AR since its aim is not simply adopting a detached approach to a practical problem. Rather, AR in this instance is applied simultaneously to the researcher (first person), the second person relationships the researcher is engaged with, and, on the third-person, institutions that may be implicated in the issues being addressed. Accordingly, this perspective should lead to both changes of consciousness (through new realizations/interpretations of reality) but also cultural transformations.

Living educational theories: This perspective particularly highlights the importance of the effect of the researcher and the research process on the outcome of the research and accordingly, encourages transparency and honesty about these two dimensions. This approach encourages the researcher to be authentic about his/her views and subsequent transformations highlighting associated existential and spiritual issues.

Summary and Future Directions

As stated above, AR has come to reflect a family of approaches whose main thrust is to make research accessible to practitioners be they educationists, psychologists, sociologists, or managers. One of the challenges is how to ensure that such variety of approaches will not be considered equally valid alternative approaches given the various levels of foci since clearly approaches with multiple level of foci are much richer in clarifying issues and tend to be more robust in deriving solutions than some approaches that may be simply focused at one level of the problem.

The issues of “objectivity” of research outcomes have been raised and will still be raised, by the puritan positivists who leveled the charge that AR is too subjective. However, the response is that action researchers usually deal with social issues and, as such, such subjectivity is very much the target of many problematic practical situations and may need observing in their natural environment. Addressing the imagery, opinions and perceptions of stakeholders are necessary steps of helping to resolve practical issues such as emotional coping or understanding the values that underpin certain social behaviors.

The last point is very much linked to the context of AR in addressing a sustainable issue. While some experimental types of research may help identify sources and effect of some environmental problems, it is clear that understanding multifaceted dimensions of human behavior may require the input of various practitioners helping address a problem that may be affected by several factors. Accordingly, sustainability issues require

an army of researchers working in various contexts using various techniques. This means that environmental researchers will require an armamentarium of methods and techniques from which they will be able to choose those relevant to the problem at hand.

AR has come a long way from being just seen as an adjunct approach to what came to be termed “qualitative/soft” methods, to being seen as a valid approach that may entail the use of multiple quantitative and qualitative techniques.

Activism

► Shareholder and Stakeholder Activism

Activist Investor

Maria Aluchna
Department of Management Theory, Warsaw
School of Economics, Warsaw, Poland

Synonyms

Activists; Investor activism

Definition

An activist investor is defined as an individual or group who acquires a stake of shares in a publicly

listed company with the intention to have the influence over it (Nordberg, 2010; Larcker and Tayan, 2011). The size of the stake enables such person or a group an active participation in decision-making over the company strategic development, investment, and profit distribution. Exercising their rights as partial owners, activist investors challenge executives, engage in the discussions on corporate matters, and submit proposals of the resolutions to be voted during the shareholder meeting (Tricker, 2015).

With the stakes held, activist investors are more likely to get appointed to the board in order to have the access to information about the company operations and have a real influence on the possible changes. They can also motivate and coordinate the actions of other shareholders. They pressure for the procedures on effective governance such as the board work and appointment, assessment of corporate performance, review of strategy, and structuring executive compensation. However, some activist investors do not hold significant stakes in ownership but play a very active role in the dialog with executives and submit many shareholder proposals. Such activists include well-known prominent private investors or high profile asset managers. Examples of activist investors include pension funds, institutional funds with a social or environmental mission, hedge funds, and individual investors (Larcker and Tayan, 2011).

Introduction

The concept of investor activism has been developing in line with the fundamental assumption that the effective monitoring and control may enhance firm value. Numerous studies have shown that coordinating actions by shareholders and their engagement in oversight over executives provide discipline and enhance firm value (Shleifer and Vishny, 1997; Black, 2018).

According to studies on ownership structure in the 1980s, the percentage of shares held by institutional investors in an average American corporation surpassed the percentage of shares held by individual investors (Useem, 1996). This process

gave rise to the engagement of institutional investors in the US corporate governance due to the size of their stakes, their expertise, and know how as well as the ability to pressure executive boards (Maug, 1998).

The development of corporate governance guidelines, specifically addressing the practice of the board, the structure of executive compensation, and the standards of transparency laid further grounds for investor activism. With waves of corporate scandals and analysis of corporate governance inefficiencies, a list of recommendation to assure for effective monitoring and governance was formulated. The emergence of professional ratings evaluating the quality of corporate governance of a company (e.g., MSCI) brought the more quantitative element to measure the board practice, executive remuneration structure, company relations with auditors, and the exercise of shareholder rights (Skougard, 2017). Investors could assess the quality of corporate governance in companies and suggest required changes based on the assumption that these changes would enhance firm value (Renders et al., 2010).

Investor activism has developed in the largest and most liquid stock markets which due to the legal regime of common law assure for strong investor protection. Investors are motivated for active engagement in monitoring and control as they are provided with detailed information about companies (high transparency standards), are given the right to engage in class action, and may sue the management if creating shareholder value is threatened and may exert voice via proxy voting. In countries characterized with significant ownership concentration, blockholders are naturally involved in the oversight over company performance (Shleifer and Vishny, 1997; Berglöf and Claessens, 2006), and if dissatisfied they can remove the executives and impose a different strategic direction. Such actions are naturally constrained in the environment of dispersed ownership which is characterized with the separation of ownership and control, and information asymmetry as well as the risk of executive acting at the expense of shareholders.

The role of activist investors significantly depends on the national system of corporate

governance and shareholder structure. Market-based model of corporate governance, deep and liquid stock market, and dispersed ownership give rise to the development of power of activist investors (Bainbridge, 2012). Corporate governance based on hierarchies, concentrated ownership, and the dominance of families limit the opportunity for outside investors to play a significant role.

The Development of Activist Investors

Distinct types of investors have different goals and expectations expressed in their investment strategies (Aluchna & Kamiński, 2017). Investors reveal the whole spectrum of the activity level ranging from passive investors to involved investors and activists depending on a number of factors. Nordberg (2010) distinguishes three dimensions of shareholder politics which determine different actions and campaign activism may engage into:

- Attitude which refers to the investment strategy of buy, sell, and hold.
- Participation which addresses the degree in which investors decide to engage in having influence in a company ranging from passive to active. This criterion may also be used to differentiate investment strategy between passive such as index-tracking and active investing Wall Street Walk and views active reaction and selling shares in the moments of disappointments with company performance as a version of activism (Edmans, 2009).
- Horizon which indicates the perspective of the investment with respect of time ranging from short-term to long-term investment.

Table 1 presents the set of determinants of engagement by institutional investors as identified in the OECD study.

As shown in Table 1, large group of ownership investors may be categorized according to several criteria such as purpose, investment strategy, and objectives. Activists tend to have quantitative approach, to follow diversified investment strategy, and to have short term for profit orientation.

Activist Investor, Table 1 Determinants of ownership engagement

Purpose	Not for profit		For profit	
Liability structure	Long term		Short term	
Investment strategy	Passive, index	Passive, fundamental	Active, fundamental	Active, quantitative
Portfolio structure	Concentrated		Diversified	
Fee structure	Not applicable	Performance fee	Flat fee	Zero fee
Political/social objectives	Political/social incentives		No social/ political incentives	
Regulatory framework	Engagement requirements	Engagement limitations	No legal requirements/ limitations	

Source: Celik S., Isaksson M. (2013). Institutional investors and ownership engagement, OECD Journal: Financial Market Trends, 2013/2, 93–114, <http://www.oecd.org/corporate/Institutional-investors-ownership-engagement.pdf>, 105

Corporate governance studies focus predominantly on the impact of profit-motivated investors. While the typology presented in Table 1 assumes that passive investors reveal not for profit orientation, some of them, as index funds, focus on generating returns based on investment in a pre-determined index (Larcker and Tayan, 2011). Active investors reveal a dynamic approach to investment strategies searching for the best outcome. Yet, these investors, in the case of disappointment with company performance, may choose between two general strategies – exit and vote. The exit or reduce approach refers to the withdrawal from the investment of given companies in reaction to poor performance. Contrary to the exit strategies, satisfied and interested investors may pursue, maintain, or accumulate strategy.

The alternative approach refers to the active engagement in voting or a number of other actions. It is based on the fundamental assumption that such interventions result in better performance and higher return on investment. Activists often participate in shareholder meetings and launch campaigns which exert pressure on management and suggest corporate governance reforms (Tricker, 2015).

Historically, investor activism is linked to the strategies adopted by US pension funds (e.g., CalPERS, TIAA-CREF) which after acquiring a stake of shares intervened in the targeted companies (Blair, 1995; Mallin, 1998; Monks and Minow, 2004). Tricker (2015) discusses that in the early twentieth century shareholder democracy was limited as the separation of ownership

and control identified by Berle and Means (1932) moved power from shareholders to management. After the takeover era and in line with the growing presence of institutional investors such as pension funds and investment funds in shareholder structure, the balance of powers started to change (MacAvoy & Millstein, 2003; Davidoff, 2009; Bainbridge, 2012) and gave rise for investor activism. Pension funds tended to focus on companies which were undervalued or revealed significant inefficiencies on corporate governance (Woitke, 2002). With the proposal to reform shareholder statutory rights, board structure, or replacing CEOs, pension funds proved that activism is not only possible but that it can also lead to changes in corporate governance and enhance firm value. Their interventions had an impact on the board previously dominated by executive directors and the strong positions by CEOs who often serve as Board Chairman.

Over years, shareholder activism has changed the ways control and monitoring function. First, many financial and social investors actively monitor executives and participate in annual shareholder meetings submitting different proposals. With the technological development, companies introduce the e-voting that allows shareholder to participate in the shareholder meeting without the need of physical presence. The activism of investor takes also other forms of actions. Investors participate in roadshows and meetings with the company executive teams and write letters to management. In addition, there are specialized companies and advisory groups which support

shareholder in exercising their rights by providing the expertise or offering the representation at the shareholder meeting. This allows potentially dispersed shareholders to act collectively and increase their position.

Second, investor activism is not limited to traditional financial institutions. Holding companies, hedge funds, or private equity funds led by prominent individuals, including Carl Icahn, Nelson Peltz, and Bill Ackman, are among the most active and influential investors with significant impact over the company strategy and governance procedures. The presence in social media as well as general public trust strengthens the power of active investors who may challenge executives with respect to company performance and profit-sharing policy (dividend payouts, stock repurchase). As more capital is accumulated in different types of investment schemes, funds gain more impact on companies holding numerous stakes. It is estimated that nowadays 75–85% of shares of listed companies in the USA and UK are held by financial investors. Even if not all of them are actively engaged in monitoring, still the overall impact by shareholder is growing.

Third, while in the early days investor activism focused mostly on M&A transactions and corporate governance-related issues, today more topics are on the table. Shareholder proposals may include restructuring, strategic redevelopment, environmental protection, divestment from politically sensitive parts of the world, working conditions, or diversity management. The scope of investor activism is discussed in the following section.

The Size and Scope of Investor Activism

In recent years, reports have been revealing the growing interest in shareholder activism calling it the megatrend in corporate governance. It is not only the activism itself that “is as strong as it’s ever been” has been increasing (Skorupa, 2017), but also the impact that activism has on companies operation, governance, development, and CEO turnover (McKinsey, 2014). McKinsey reports that there are around 550 “active activists” around

the world controlling more than 180 billion USD (McKinsey, 2014). They operate mostly not only in the USA but also in Europe, Australia, Canada, and Hong Kong where they cooperate with assets and pension fund managers to reform corporate governance. JP Morgan estimates that approximately 13% of US companies with market value over \$10 bn are subject to activist campaigns (JP Morgan, 2019).

According to Schulte Roth and Zabel (2019), in 2018 activists targeted 922 companies with over a half of cases (491 cases) in the USA. This is an increase from the previous years when 856 (in 2017) and 887 (in 2016) cases took place. Activists focused on small cap (25% of actions taken), nano cap (23%), and large cap (20%) companies. With respect to the sector of operation of targeted companies, services dominated the sample with 22% of cases followed by finance (20%), basic materials (15%), and technology (13%). The activism took the form of monthly occasional focus with 36% of targets followed by concerned shareholder approach with 35% of cases (Schulte Roth & Zabel, 2019).

A different publication by Lazard’s Shareholder Advisory Group (2019) 2018 Review of Shareholder Activism reveals that 226 of companies were targeted in 2018 by activist investors as compared to 188 firms in 2017 with \$65.0bn of capital deployed. The review also reports a record 131 investors engaged in activism in 2018 with nine of the top ten activists investing more than \$1bn in 2018 (60 new campaigns in aggregate). Against the backdrop of a robust M&A market, 33% of 2018 activist campaigns were M&A related.

Besides the increase in the scale of activism, investors broaden the scope of their actions. Investor activism often takes the form of taken actions and proposals submitted during the annual (general) shareholder meeting. These actions may refer to blocking decision submitted by management team on mergers and acquisitions, decisions on capital structure (stock splits), profit-sharing policy (dividend payouts, stock repurchase), and valuation in divestiture transactions. Campaigns launched by investors cover also corporate performance specifically emphasizing the level of costs,

rigidity of the corporate structure (e.g., in holdings), and introducing restructuring plans and reforms. Other issues raised by activists refer to the functioning of the board or the practice of executive compensation. The main focus of activist is to eliminate company bylaws or rules that constrain equal treatment of shareholders, for instance, activist support majority voting or proxy access.

Specifically, with respect to the board practice investors engage in the so-called shaming and naming actions which refer to the public criticism of executives or directors (Nordberg, 2010). Such campaigns address the appointment of directors and executives to the board, the removal of staggered board, and increased board disclosure (self-assessment report with the information of board meetings and directors attendance). Investors emphasize the importance of having well-experienced and active directors and call for increasing diversity on board and growing awareness of ESG challenges.

For reshaping boardroom activists adopt three main tactics: proxy fights, long slates, and litigations (Lazard's Shareholder Advisory Group, 2019). Proxy fight is defined as an action of a group of shareholders joining forces, in a bid to collect enough shareholder proxies to win a corporate vote. Long slates are understood as situations where an activist nominates directors to replace 50%-plus of the incumbent board. Litigation means that the case between two actors is taken to court for the final resolution.

Activist investors often target the topic of executive compensation calling for higher transparency on the evaluation procedure of executive work (financial measures, nonfinancial indicators), proper balance between short, medium, and long-term goals and incentive schemes.

M&A transaction is another area of a particular interest of activist investors. Their campaigns refer to three main topics of selling a company to consolidate business, break-ups, and divestiture to limit the scope of corporate strategy as well as entering into live M&A situation to improve deal terms or block an ill-perceived deal from

proceeding. Activist campaigns address also the forecasts of the M&A efficiency (Lazard's Shareholder Advisory Group, 2019).

Although activist investors belong to the most aggressively acting shareholders, they may motivate traditional investors to support their campaigns and introduce changes in the board structure or decide about the M&A transaction. Table 2 presents selected public campaigns launched by activists.

As reported in Table 2, the actions undertaken by activist investors are often not very well welcomed by company executives or even by other shareholders. This means that activists need to engage in negotiations while their actions require a lot of efforts. As reported by JP Morgan The 2018 Proxy Season 37 fights in the USA were resolved with settlements, the most frequent single outcome, which is an increase from 28 in 2017, while dissidents succeeded at least partially in 56% of 2018's contests as compared to 43% in 2017. In addition, many of the suggestions raised by activists do not end up in voting or are not included in the shareholder meeting agenda, for instance, in 2012 when Carl Icahn expected Apple executive to deploy higher funds for additional stock repurchase claiming that the company stock was undervalued. Due to reservations by the executives and some board directors, eventually Carl Icahn decided to withdraw this proposal from the shareholder meeting. Such move allows to avoid a conflict with executives.

Investor activism takes different forms (Tricker, 2015) – from announcement, press conferences or releases, and letters to shareholders or to management to starting a campaign, calling for intervention, restructuring or executive replacement, and active participation at the shareholder meeting.

The largest activist investors include three funds operating on the global scale: Elliott with \$14.7 of the market value of positions launched in 2013–2017, ValueAct with \$12.6 bn and Cevian with \$11.2bn (Lazard's Shareholder Advisory Group (2019). They are followed by investors focused on the activity on the American market including Trian with \$11.1 bn, Third Point with

Activist Investor, Table 2 Selected public campaigns launched by activists

Launch date	Company/ market cap	Activist	Highlight
USA			
October 2018	Dell VM ware (\$18.9bn)	Icahn enterprises, Elliott	Icahn opposed offer from Dell to buy VMware tracking shares due to insufficient price. The fund relented after Dell increased its offer and won support from Elliott and canyon capital
March 2018	United technologies (\$97.8bn)	Third point	Pershing Square and third point urged United Technologies to break itself into three businesses. After receiving clearance for a merger with Rockwell Collins in November, United Technologies announced it would separately spin off its carrier and Otis businesses
Europe			
December 2018	Nordea (\$34.2bn)	Cevian capital,	Cevian pressured Nordea significantly reduce costs to bring the Company's performance in line with its Scandinavian peers
May 2018	ThyssenKrupp (\$15.8)	Cevian capital, Elliott	The company CEO and Chairman resigned in July 2018 as a result of pressure from Cevian and Elliott. In September, the Company announced the separation of its marine and industrial solution businesses

\$9.4 bn, and Icahn with \$7.9 bn of the market value of positions launched in 2013–2017. Other sources point also at Jana Partners and Starboard Value, Legion Partner Asset Management.

Benefits and Criticism of Active Investors

The development of activist investors was based on the assumption that the involvement of institutional investors in governance may lead to better performance and produce a higher return of investment. Over years, a number of studies have been revealing various results raising some questions on the efficiency of institutional investors in general and activists in particular. Below the most important aspects of benefits and criticism are discussed.

Studies indicate positive (Romano, 1993, 2006) or little positive (Bainbridge, 2012) evidence of institutional investors engagement in governance. Due to their experience, know-how, and professional knowledge, institutions provide oversight and monitoring over the executives (Nagel et al., 2015), discipline executive, and exert pressure on dominant owners in countries

characterized with concentrated ownership. Active shareholder policy improves monitoring of corporate spending, reduces manipulation of management earnings, lowers the size of executive compensation, supports governance reforms, and addresses social and environmental issues (David et al., 2007). Activists most often target companies who are underperforming, particularly lagging the industry benchmark with large cash balances and recurring restructuring charges (Cyriac et al., 2014). In result, positive effect on performance is noted. These positive effects are also observed for activists who motivate executive for restructuring corporate governance reforms and improve performance in targeted companies (Dai, 2014). Actions undertaken by activists are beneficial also to other shareholders (Cyriac et al., 2014).

Activist investors are also seen as an important element of stock market as by rising important topics they can motivate universal owners (institutional investors) to actively support key proposals on corporate governance, restructuring, or M&A deals. According to Gilson and Gordon (2013), in that way activist investors may help reconcentrate power from institutional investors.

Finally, activist investors add to increasing liquidity (Back et al., 2018).

The role of activist investors can be also controversial. First, traditionally researchers questioned the actual engagement and impact investors can have on companies. As mentioned above, investors differ in goals and expectations as well as in monitoring strategies and governance behavior (Woidtke, 2002; Chen et al., 2007) that may be mirrored in different strategies in campaign launched by activists and in proxy fights. Second, activists, as other investors, are the source of another agency problem. They represent and act on behalf of their customers and may have different interests (Gilson and Gordon, 2013). They may also be subject to principal-agency problems and information asymmetry. Studies on institutional investors show some concerns are raised on the actual effect on performance, particularly long-term performance. Particularly activists tend to be short-term oriented, and their actions may be detrimental to long-term focus value creation. This argument however was not recently supported. Bebchuk et al. (2015) noted that there is no evidence suggesting that interventions are undertaken by activists followed by short-term gains in performance that come at the expense of long-term performance.

Activist Investors and Sustainability

Traditionally, activist investors were focused on financial performance and increasing shareholder value. The campaigns target underperforming companies which offer possibilities to higher return on investment once restructured. Taking into account the engagement of the activist investors in the ownership structure or their overall reputation and impact on the investor community, activists could encourage other shareholders to support their proposals. Potentially, these proposals can refer to sustainability performance and disclosure and well as to strategic decisions which incorporate ESG dimension. Still however, evidence on such proposals remain scarce, adding to potential avenues for future research.

Summary

An activist investor is an individual or group who acquires a stake of shares in a publicly listed company with the intention to have the influence over it. Activist investors include pension funds, institutional funds with a social or environmental mission, hedge funds and individual investors. Activists possess a stake in company ownership that enables such person or institution to have influence in decision making over the company strategic development, investment and profit distribution. Exercising their rights as partial owners activist investors challenge executives, engage in the discussions on corporate matters and submit proposals of the resolutions to be voted during the shareholder meeting. Since they are often well know members of the investor community, they are likely to encourage other shareholder to support their proposals and implement changes in the targeted companies. Their primary focus is to improve financial performance of the company and increase shareholder value. Yet, activist investors have the potential to submit proposals related to ESG performance and disclosure.

Actors of Development Management

F. Sciarelli

Department of Literary, Linguistic and Comparative Studies, University of Naples “L’Orientale”, Naples, Italy

Synonyms

Country growth players

Definition

The term actor comes from the Latin actor which is none other than the noun derived from the Latin verb *agere* which means to act: the actor is the one who acts. The actors of the development are all those organizations, institutions, and people that act for the human development of the territorial areas. There are therefore different types of actors in the system: main, secondary, and support actors; global, regional, and local actors; intergovernmental, governmental, and non-governmental actors; economic and social actors; traditional and emerging actors. In many cases, the same organization has multiple roles within a development process. For these reasons it is not easy to provide a classification of the type of actors of a development process that is exhaustive, without losing clarity and effectiveness. For these reasons we theorized the Development Actors Matrix: the matrix of actors that can play different and even multiple roles for country development. In fact they can be proactive actors, support actors, economic sources, and process and controller regulators.

Key Issue

We therefore chose to distinguish the organizations that participate in the development process of weak areas according to two fundamental characteristics: (1) the “legal” nature, divided into public, private, and mixed and (2) the area of action, divided into global, regional, and local (Fig. 1).

Public actors include all those organizations that have exclusively public legal nature.

These actors can be divided by their geographical area of action, in international, regional (Garcia, 2015), and local, and further subdivided through the type of activity carried out for the human development of the weak areas of the world.

Among the public actors, we distinguish: global and regional intergovernmental actors and governmental actors. Intergovernmental actors correspond to those structures that are founded by several governments at the same time. These structures may include governments located in multiple continents (global intergovernmental actor) or in a single continent (continental intergovernmental actor) or in a specific geographical, religious, or cultural area (regional intergovernmental actor).

The governmental actors are, instead, those organizations founded by a single government, such as government commissions, public universities, public enterprises, etc. Obviously, in this case, there are only national or subnational actors.

In an overall system of development of a country, the public actors of international development are necessarily joined by those not tied to governments, independent, sometimes linked to the market. These are the NGAs (nongovernmental actors).

They include all the actors involved in the development of the transforming areas that do not have binding relationships with governments (Anheier, 2011; Salamon and Anheier, 1997), i.e., NGOs, companies, social movements (Cesareo, 2003), private universities, private foundations (Andrews, 1956; Lundsgaarde, 2010; Srivastava and Oh, 2010), etc., like Save the Children and the Bill and Melinda Gates Foundation. These can correspond to global, regional, or local organizations.

Actors of Development Management,

Fig. 1 Development actors matrix (Sciarelli and Rinaldi 2017a, b)

		Nature		
		PUBLIC	PRIVATE	MIXED
Geographical Area	GLOBAL	<i>Intergovernmental Global Actors</i>	<i>Multinational Non Governamental Actors</i>	<i>Global PPP Network</i>
	REGIONAL	<i>Intergovernmental Regional Actors</i>	<i>Regional Non Governamental Actors</i>	<i>THO Network</i>
	LOCAL	<i>Governamental and Local Public Actors</i>	<i>Local Non Governamental Actors</i>	<i>Local PPP Network</i>

Lastly, we have public-private actors (Argueta de BARillas and Gomez, 2014), i.e., foundations, associations, commissions, and companies that are founded on partnerships between public actors and private actors, such as the Global Fund for Fighting AIDS.

Collective actions for international development have greatly increased in the last two decades. Many of these have been realized and are realized in the creation of new global partnership organizations (Missoni and Alesani, 2014). Public-private partnerships (PPPs), which involve both public and private organizations, are essential especially when the urgency of acting to resolve a particular humanitarian issue exceeds the speed and capacity of traditional institutions to respond effectively. The mandates of the majority of these organizations, in fact, face a specific challenge or a specific problem (for example, vaccinations, the main infectious diseases, and primary education). Because of this, they are

generally referred to as vertical organizations or vertical funds.

All these actors can then play different and even multiple roles. For example, they can be proactive actors, support actors, economic sources (Nelson, 2013), process, and controller regulators (Sciarelli and Rinaldi, 2018).

Summary

The actors of the development are all those organizations, institutions, and people that act for the human development of the territorial areas. There are therefore different types of actors in the system, in many cases, with multiple roles. All players are fundamental for the territory development. They are sometimes initiators, sometimes supporters, and sometimes operatives. In the development phases of a country each actor has a different role and this itself changes from phase

to phase. The activities of Intergovernmental Global Actors, for example, are completely different in the Start up phase than Hang on phase or Self development phase. The importance of the matrix is to put all the players in order to identify, with great attention, their role in the phases of the Overall development model.

Adversarial Ethics

Xavier Landes
Stockholm School of Economics in Riga,
Riga, Latvia

Synonyms

Competitive ethics; Ethics of adversaries

Definition

Adversarial ethics is a relatively recent field of morality, which is concerned with competitive behaviors, such as in sports, politics, business, the judiciary system, or, ultimately, war. Its aim is to determine the conditions to be imposed on competition for rendering it acceptable. It constitutes a departure from “traditional ethics” and from its focus on the principles and constraints to be applied to individuals when they cooperate or interact in a neutral manner (neither competitive nor cooperative). In contrast, adversarial ethics deals with situations where individuals and organizations should not intend to collaborate, when they unapologetically pursue their self-interests. Most of such situations are socially codified and circumscribed, e.g., sports, business, or politics. Moreover, they are accepted insofar as they generate positive outcomes of some sort (for instance, a thrilling spectacle, lower prices, products of higher quality, better qualified representatives, truth in court). Thus, adversarial ethics could be understood in a consequentialist way as a set of reflections about how to bound competitive behaviors in a manner that maximizes social benefits. However, the approach could be criticized as fueling moral drifting or relativism. Finally, it might be claimed that adversarial contexts, although genuinely specific in nature, do not justify as much departure from common morality than it is often assumed.

Introduction

Ethics is the field that reflects on the mutual obligations of human beings. Traditionally, it has dealt with the imperative of and conditions for goodness, fairness, or reciprocity among people who cooperate or who interact on a daily basis. Most approaches rely on principles enjoining agents to be kind or generous, to do good, to treat others with respect or reciprocate.

Nevertheless, human relations are not always characterized by kindness, generosity, or cooperation. Furthermore, in specific situations,

individuals are not expected to be kind or generous. For example, opponent teams during a football tournament are not expected to be kind or “collaborate.” Political adversaries who run for the same elected office are not expected to be nice toward each other. Any occurrence where competitors seem to band up together raises the suspicion of collusion, of a rigged game.

Thus, there are situations where individuals compete for winning, for accessing to goods, for gaining votes or customers, and for pushing their rivals out of office or business. The confrontation could be violent and nasty, for instance, between mafia organizations with threats, pressures, and killings, or it could take milder expressions like in sports. Some competitive structures are accepted (e.g., in politics or sports), while others are repressed (e.g., between mafia organizations).

Regarding the former, traditional ethics offers little guidance when it comes to determine the boundaries of tolerable attitudes and behaviors. The reason is that traditional ethics, by definition, is meant to eschew or lessen rivalry and force individuals to adopt a cooperative or a benevolent stance. For example, the Kantian categorical imperative is mostly ineffective for separating acceptable from unacceptable types of competition on a football pitch. It is unclear how the principle of universalizability could apply, at least the argument goes.

Adversarial ethics is presented as a response to such a lacuna. It is a field that takes seriously the specificity of the context (competition, noncooperation) and reflects on the potential obligations that must bind antagonists. To some degree, it relies on the assumption that the social (and, therefore the moral) life can be divided into spheres where norms vary depending on the sort of interaction that define each of these spheres.

The Moral Specificity of Competition

First, adversarial ethics posits that cooperative and competitive settings differ in a *morally significant manner*. In the former, individuals interact with the objective of pursuing their conception

of the good while benefiting from each other. Examples include working in an organization such as a company, a ministry, or a nonprofit organization. Members usually share a common goal (e.g., developing the best products, devising policies, providing public services or advocating for specific rights) and, consequently, are expected to adopt a mutually beneficial or at least non-detrimental strategy.

To this first category, neutral settings could be added, where people neither collaborate nor compete. In most of these situations, non-interference is the default position. Individuals are expected not to interfere into someone else's life or course of action *without good reasons* (e.g., to end negative externalities such as pollution). For example, individuals are entitled to enjoy their property without arbitrary interference as long as they do not threaten or hurt anyone, as stipulated by the harm principle (Mill 1859).

In contrast, competition encompasses situations where agents meddle, to some extent, into each other's plans. They oppose, conflict, and clash. Furthermore, any suspicion of either cooperation or noninterference is likely to be lambasted. For instance, when teams rig a match, it is viewed as a violation of the "spirit of the game," a collapse of good "sportsmanship," and, ultimately, a sign of moral corruption (e.g., the fixed game between West Germany and Austria during 1982 FIFA World Cup that provoked the elimination of Algeria).

Adversarial situations are contexts where rivals are expected to compete for the sake of some higher "good," broader benefits, or "positive externalities" (Norman 2011). Companies operating on free markets aim at taking away their competitors' clients, revenues, market shares, and so forth. Consequences are revenue losses for those falling behind, employees laid off, or bankruptcy. In an open democracy when politicians compete for elective positions, they actually try to oust incumbents or bar other people from getting a public office. Access to resources, prestige, and power is at stake, and the defeated side is at risk of being cut off from these advantages.

Thus, adversaries hurt each other. Politicians are claimed to be incompetent or self-interested, damaging their reputation. In virtue of the rotation of political representatives, they regularly become unemployed. Their private life might be exposed. They might be accused of being vicious and inept or of suffering from poor judgment. Occasionally, the competition ramps up, and allegations of treason, misconduct, or even embezzlement are laid.

Rivalry pushes firms out of business and leads to people losing jobs, income, and often other benefits (e.g., health insurance, pensions). Joseph Schumpeter's concept of "creative destruction" (Schumpeter 1994) acknowledges this ambivalent dynamic at the core of capitalism where companies fail, markets decline, and crises happen. Creative destruction is tolerated because it clears the ground for new economic initiatives and ideas. Criminal legal procedures result in exchange of accusations, exposition of people's private lives, and sometimes lies and humiliation. Sports constitute zero-sum games where one side wins what the other loses (e.g., points in a championship, trophies, place in the tournament).

The very existence of harm, and its social acceptance, is at odds with "traditional" ethics which instructs, for instance, to treat another person "as an end, never merely as a means" (Kant 1997), to act in a way that they maximize pleasures, happiness, or positive outcomes and minimize pain, unhappiness, or negative outcomes (for utilitarianism or consequentialism). It is difficult to deny that even in adversarial contexts, there is some duty of respect, usually related to the "spirit of the rules" or fair play. However, it is unclear how rivals should treat each other as ends in themselves without drastically altering or, worse, suspending competition (e.g., fixed games). More broadly, competition seems to shake the very foundations of ethics, by tackling the widespread obligation to do good.

Adversarial ethics then emerge as the attempt to directly derive principles and constraints from the nature of competitive settings for rendering them more "ethical" or acceptable. It could be interpreted as a tentative to grant exemptions from general moral rules (e.g., not lie, not harm, cooperate) for the lawyer defending her client

in court, a tennis player at Roland Garros, or a politician running for president *while securing the benefits society extracts from rivals endorsing their “role.”*

Adversarial ethics raise the issue of contextualism. It suggests that the context, the “role” that befall on antagonists, matter for moral evaluation. The “context” refers to the competitive conditions in themselves but also to the wider environment. A presidential election is a particular setting, institutionally devised, that performs a specific function in the broader frame of open democracy: *letting candidates chosen by their party competing through a rational exchange of arguments in order to cater to voters evidence about their adequacy as potential head of the executive branch.*

Another illustration is provided by Adam Smith (1993). His idea is that the ultimate justification for markets (so competition) lies in their capacity of channeling self-interests into realizing the common good. He famously posits that markets act as they are guided by an “invisible hand” that coordinates the diversity of egoistic motives for satisfying everyone’s needs and contributing to improving social welfare. Adversarial ethics could be viewed as a voluntarist enterprise to support the multitude of invisible hands. It achieves that by devising obligations that derive from a close attention to the conditions under which competition creates net benefits. It formulates constraints on antagonists for keeping their strategies within the limits of what is socially beneficial.

Competition needs to happen in such a way that its “virtues” are preserved, i.e., that the actual behavior of rivals does not undermine the social benefits expected by the society from particular competitive settings. In other words, adversarial ethics try to optimize the positive consequences of competition in relation to the negative ones for each specific setting.

On markets, the main social benefits include low prices, innovation, quality products/services, and adequate information. These are the outcomes to be expected when companies compete in a proper manner. Such benefits could be subsumed under the principle of “market efficiency” in the

sense that well-devised moral limits contribute to improving Pareto efficiency (i.e., when the situation of at least one agent is enhanced without anyone else being made worse off).

As indicated above adversarial ethics consists in constraining competitive settings for maximizing the probability of positive consequences and minimizing the negative ones (efficiency). This explains why false advertising or price dumping is deemed unethical, because they impair the expected social benefits by conveying deceiving information, artificially keeping prices low the time to get rid of the concurrence, and so on. Moreover, those shortcomings are likely to generate misallocations of productive resources (i.e., capital and labor).

The positive outcomes of electoral competition are to offer pertinent knowledge on candidates’ ability to govern, provide a channel to the expression of political pluralism, and so forth. If politicians lie about their credentials, partake in ad hominem attacks, and cover up their real intention (e.g., be at the service of some powerful lobby at the expense of the common good), they tarnish the signals received by citizens and dampen the quality of the debate. They distort the information collected by voters and pervert the expression of pluralism.

For sports competition, individuals and teams are expected to genuinely try to win by respecting the game’s rules *and* spirit. For instance, their performance needs to flow from their efforts, wits, strategy, preparation. and, perhaps, a dose of luck, not from gaming the rules, bribing referees, or colluding with rivals. If they indulge in one of the latter, they degrade the quality of the spectacle, spoiling the experience of the spectators and, ultimately, being accused of ruining the game.

There have been sparse tentatives for devising what adversarial ethics requires in specific competitive contexts. Drawing an analogy with sports, Joseph Heath (2014) offers one of the few attempts to elaborate adversarial principles for business. Morally acceptable market competition should conform to five rules: do not exploit market failures (e.g., pollution), do not cheat (i.e., respect the law, for instance, by not engaging in

tax evasion), do not game the rules (i.e., follow the spirit of the rules, e.g., by not avoiding tax), take the high road (the fact that its rivals violate the rule does not excuse for any lapse), and do not lobby against regulation that aims at fixing market failures (because then the social benefits of competition are undermined).

An objection is to underline the risk of ethical drifting. The contextual nature of adversarial ethics could be interpreted as granting a license to specific actors (e.g., companies, politicians) not to follow at all (or selectively) the rules of common morality such as not lying, not harming others, and so forth. Adversarial ethics would then be used as an excuse for obviously wrong or bad behaviors that, in other circumstances, will be condemned.

A variant of the objection is to raise the danger of relativism in a society where diverse social, competitive and noncompetitive, spheres would be governed by different, potentially conflicting standards. The worst-case scenario would be the emergence of a fragmented ethical landscape. In such a situation, it would become difficult to hold rivals accountable for their actions.

A possible answer is to assert that adversarial ethics cannot be equated to moral relativism or drifting. The reason is that, even though the context matters for devising antagonists' duties, the context is not the only thing that matters, the only source of normativity. The overall social benefits of the adversarial settings matter. Other obligations, extracted from daily morality, also matter. For instance, it is absolutely forbidden for a company or a football team to murder their competitors. Lying is actually not tolerated (at least not justified) for corporate or political communication.

A broad conclusion could be that although adversarial situations represent indeed specific contexts and although such contexts may grant some ethical modulations, they justify more modest departures from common morality than often assumed (Applbaum 1999). Therefore, rivals should benefit from less latitude for engaging in harmful, coercive, or deceptive behavior.

Summary

Adversarial ethics is the field of moral reasoning that covers contexts characterized by competition, i.e., situations where individuals are not expected to cooperate or, at least, to interfere into someone else's life. It refers to contexts like market or political rivalry, sports, or the judicial system. It has two traits. First, it represents a departure from "traditional" or daily morality which imposes to agents some degree of benevolence, generosity, cooperation, and so forth. Second, it justifies such a departure from the setting in which the adversarial interaction takes place by invoking the social benefits of competition, thus positing that specific situations could require specific duties and exemptions. These two characteristics are subject to criticism from those objecting to the moral autonomy of competitive settings and, therefore, the salience of adversarial ethics.

Positive action; Positive discrimination; Reservation (in India)

Definition

Affirmative Action (AA) is a debated topic in many fields of study; however, psychology and juridical research have paid major attention.

AA consists of a body of policies and procedures aimed at eliminating discrimination at work against women and ethnic minorities, and repairing the effects of discrimination suffered in the past (Kravitz et al., 1997, p. Vii cited by Kovacs et al., 2014). However, in a wider sense, it can include all policies and actions to promote opportunities for disadvantaged (or minority) groups to give them equal access as the majority population within a society (e.g., Sowell, 2004).

Indeed, AA is often adopted by governments and educational institutions to ensure that those groups within a society are able to take all the opportunities offered, including promotional, educational, and training ones. Usually, AA takes the form of policies for targeted recruitment programs, preferential treatment for disadvantaged groups and, in some cases, the use of quotas.

Disadvantaged groups vary based on the national contexts; however, typically, they are identified according to gender, ethnicity and/or disability or their status, conceived as a combination of education, income, and occupation.

Introduction

Origins of AA date back to the United States (US) Reconstruction Era, 1863–1877 (Urofsky, 2020). Successively, Executive Order No. 10925, signed by President Kennedy in 1961, introduced AA with its current meaning by stating that government contractors take AA to ensure that job applicants and employees are treated without disparities related to their race, creed, color, or national origin (US Department of Labor, n.d.). It was then replaced by the Executive Order n. 11246, signed by President Johnson in 1965. Such document established requirements for non-discriminatory practices concerning race, color, religion, sex, or national origin in workforce hiring and treatment by US government contractors, which also apply to federal contractors and subcontractors.

The Executive Order n. 11246 has therefore been modified and further strengthened over the years, safeguarding the rights of workers employed by federal contractors – corresponding to about one-fifth of the US workforce – from discrimination based on race, color, religion, sex, sexual orientation, gender identity, or national origin, opening the path for AA provision. In particular, the subsequent Executive Decree no. 11375 in 1967 extended the protected categories by AA, such as introducing women by inserting “sex” in the list (UCI – OEOD, n.d.).

AA could assume different forms, likewise laws, policies, guidelines, and administrative practices under a government mandate and/or approved by the government. AA can also include actions taken by private companies, which reserve preferential treatment to target groups with specific attributes such as sex or skin color, to counter the effects of entrenched discriminatory practices that violate the inherent equality and deny opportunities (Feinberg, 2005).

Formerly, AA was adopted to redress and compensate for historical discrimination disadvantages. More recently, various political contexts, such as the US and the European Union, encouraged public institutions representing their populations (such as universities, hospitals, and

police forces) to adopt AA to give an example and be imitated (Fullinwider, 2018).

So far, target groups for AA have been women, ethnic minorities living in various countries, and the disabled. The content of the AA concerns achieving goals such as promoting their access to education, bridging inequalities in employment and pay, particularly in specific occupations, encouraging diversity in the workplace and culture, and redressing apparent past wrongs or hindrances.

Notably, the United Nations International Convention on the Elimination of All Forms of Racial Discrimination provides (Article 2.2) for the request of AA to the countries adhering to the convention on the rectification of systematic discrimination. It is a case of legitimate differentiation under the Covenant to carry out activities necessary to correct discrimination (UN, 1989).

Instances of AA Around the World

AA takes different forms according to the national context. Some countries use the quota system to devote a percentage of jobs in public institutions, political positions or tuition waivers to a member of specific target groups. On the contrary, quotas based on race are illegal in other countries because it is considered an additional source of discrimination as it does not treat all people equally.

Finally, several countries devote AA to ensuring equal opportunity by, for example, targeted advertising campaigns to encourage ethnic minority candidates to join the police force, etc. (this is sometimes called “positive action”).

The following table provides an overview of the different national approaches to AA.

Reasons for and Against

Literature has massively engaged on the reasons for and against AA. The following summarizes some main arguments.

Proponents argue that AA is a form of compensation for past discrimination, persecution or exploitation suffered by socioeconomically

disadvantaged groups caused by the ruling class (overrepresented or majority groups) of a culture. Furthermore, AA addresses existing discrimination brought about by institutionalized bias or under historical conditions that caused the exclusion of minorities from education, employment, and culture (e.g., Crosby & VanDeVeer, 2000).

Indeed, such groups are disadvantaged by past oppression. In particular, the social imbalance dates back to slavery and the related laws. The AA also addresses structural racism and racial inequality to elevate the status of the perpetual underclass.

The ultimate aim is to maximize diversity at all sectors and levels of society and restore equal access to opportunities and benefits. To this end, AA seeks to achieve several objectives, including reducing employment and pay inequalities; increasing access to education; ensuring that the full spectrum of society is represented in state, institutional, and professional leadership; correcting apparent wrongs, damages, or obstacles of the past.

As for other positions in favor, Kim and Kim (2014) support that AA repairs existing unfair treatment and assures women equal opportunities, which will be consolidated in the future.

Other than the need to counterbalance historic inequality, arguments in favor of AA rely on examples of success in women, support equity and increase diversity allowing the achievement of the right of equal opportunity.

Several studies fund a positive effect of AA on advancing black, Hispanic, and white women into management, professional, and technical occupations (e.g., Kurtulus, 2012).

According to Miller (2017), in the US the number of black people among employees of private companies is equal to an average of 0.8 percentage points in the 5 years after the first regulation of AA. Surprisingly, this share continues to grow at a similar rate even after deregulation. One could argue that this persistence is partly related to improved methods for selecting potential hires induced by AA.

However, it can also lead to undesirable side-effects and consequences such as causing resentment toward its beneficiaries (e.g., Heilman,

Affirmative Action, Table 1 Approaches to AA from around the world

Continent and country	AA context	Target Groups	Provision
Africa			
South Africa	Employment	Various disadvantaged groups All people of color, women (including white women) and people with disabilities (including white people).	Companies employing more than 50 people are required to design and implement plans to improve the demographic distribution of the workforce – all people of color, women (including white women) and people with disabilities (including white people) – and report them to the Department of Labor.
Asia			
China	Education	Ethnic minorities	Universities may reduce the minimum requirements for the mandatory national exam for universities access from ethnic minorities. Some universities could set quotas system for minority student intake. Scholarships and/or tuition waivers and a monthly salary for students enrolled in ethnic minority-oriented specialties.
Israel	Employment and education	Various disadvantaged groups (Israeli citizens who are Arabs, blacks or people with disabilities)	AA civil service employment and a class-based access policy for the four-most selective university for Israeli citizens who are Arabs, blacks, or people with disabilities. Full university tuition scholarships provided by the state.
India	Employment and education	Social minorities (caste division: Scheduled Castes and Scheduled Tribes and Other Backward Classes)	Reservation of up to 50% of all government-run higher education admissions and government job vacancies for Scheduled Castes and Scheduled Tribes (SC/ST) and Other Backward Classes (OBC). A 10% quota is reserved for Economically Weaker Sections (EWS) within the remaining unreserved.
Malaysia	Various	Ethnic minorities (Bumiputera)	The Malaysian New Economic Policy (NEP) included several operations addressed to people deemed “Bumiputera” (which consists of the Malay population, Orang Asli, and the indigenous people of Sabah and Sarawak). Such operations consist of, for instance, a 30% quota for investors reserved in all initial public offerings and quotas for admission to public universities.
Sri Lanka	Education	Students from areas with lower education rates	The standardization policy established a student selection in some university faculties based on the language spoken and the district of origin to increase the enrollment of students from areas with lower education rates.
Taiwan	Employment and education	Ethnic minorities (Taiwanese Aborigines)	Firms (with 100 or more employees) wishing to become contractors for the government must have at least 1% of Taiwanese Aborigines employees. The high school or college entrance exams for Taiwanese Aboriginal students involves demonstrating some knowledge of their tribal language and culture.
Europe			
Finland	Employment and education	Language/ethnic minorities (Swedish language) Women	Some university programs have quotas reserved for highly qualified students in the Swedish language and the curriculum is partially taught in Swedish. Preferential treatment in hiring women for some public sector jobs where there is a gender imbalance.

(continued)

Affirmative Action, Table 1 (continued)

Continent and country	AA context	Target Groups	Provision
France	Employment and education	Language/ethnic minorities Students from impoverished families Women	In neighborhoods labelled “Priority Education Zones”, some primary and secondary schools are granted more funds than the others. In some institutes, students from these schools also benefit from particular policies. Some schools are obligated to take a certain number of students from impoverished families. Women must represent at least 20% (40% since 2017) of board members in all stock exchange listed or state-owned companies.
Germany	Employment	Women Disabled people	If men and women have equal qualifications, women have to be preferred for a job; moreover, the disabled should be preferred to non-disabled people.
Italy	Employment	Gender minorities	Gender equality in access to the board and control bodies of companies listed on regulated markets, establishing the less represented gender must obtain at least 33% of the members.
Norway	Employment	Gender minorities	In all public stock companies (ASA) boards, either gender should be represented by at least 40%.
Romania	Education	Ethnic minorities (Romani people)	Romani people are allocated quotas for access to public schools and state universities.
Russia	Employment and education	Ethnic minorities and inhabitants of certain territories	Preferences for some ethnic minorities and inhabitants of certain territories.
Serbia	Education	Ethnic minorities (e.g., national minorities)	The constitution promotes AA for certain marginalized groups. For instance, the Roma national minority is enabled to enroll in public schools under more favorable conditions.
Slovakia	NONE		AA is considered against the constitution
UK	Employment	Religious minority Women Other disadvantaged groups	Discrimination, quotas or favoritism due to sex, race and ethnicity among other “protected characteristics”, is generally illegal. Exceptions are listed in the Equality Act 2010, establishing the principles of equality and their implementation in the UK. Some examples include: – Police Service of Northern Ireland recruits 50% of numbers from the Catholic community and 50% from the Protestant and other communities. – All-women shortlists are allowed to select more women as election candidates.
America			
Canada	Employment and education	Women, the disabled, ethnic minorities (aborigines and aboriginal descendants), and visible minorities	Preferential treatment is established for employers in federally-regulated industries for disadvantaged groups (such as women, persons with disabilities, aborigines and aboriginal descendants, and visible minorities). Some universities offer alternative requirements for the admission of aboriginal students. In some provinces and territories, aboriginal people are given preference for jobs and education.

(continued)

Affirmative Action, Table 1 (continued)

Continent and country	AA context	Target Groups	Provision
US	Employment and education	Various disadvantaged groups	Workers employed by federal contractors and belonging to disadvantaged groups are protected from discrimination based on their race, color, religion, sex, sexual orientation, gender identity, or national origin. Some education institutions consider race as a factor when admitting students. Some colleges use financial criteria to attract underrepresented racial groups with lower living conditions. However, some states (e.g., California, Michigan, Washington) ban their public institutions, including public schools, from practicing AA (Cornell Law School, 2003).
Brazil	Employment and education	Ethnical minorities, the poor and disabled	Some universities established quotas to increase the admission of racial minorities, the poor and the disabled. In the civil public services, quotas of up to 20% of vacancies are reserved for people with disabilities.
Oceania			
New Zealand	Education	Ethnical minorities (Maori or other Polynesian descendants)	The Maori or other Polynesian descendants often have preferential treatment to access university courses or have scholarships granted.

Source: our elaboration from https://en.wikipedia.org/wiki/Affirmative_action (accessed 22 April 2022)

1996; Harrison et al., 2006). AA devalues the achievements of people selected based on the social group they belong to rather than their qualifications, thus making AA dysfunctional.

Also, arguments against AA maintain that it is based on a discriminatory assumption and would be a further new form of discrimination (a reverse discrimination form). For instance, the quota system might result in the assumption of less skilled people to the detriment of trained and meritorious staff. This could lead to unintended consequences, such as discouraging capable people from gaining high education and performing well in their studies or work. In hiring less qualified people, firms and ultimately the economy would be negatively affected.

Among the opponents of AA, it is argued that it hinders reconciliation; establishes new wrongs instead of old ones; undermines the achievements of minorities and encourages individuals to label themselves disadvantaged, even when they are not. As pointed out by Sowell (2004)

concerning race-based AA, more privileged people within minority groups benefit from AA at the expense of less fortunate people, such as middle- and upper-class blacks acquiring the benefit instead of the poor whites or Asians. Such experiences reduce the incentives to give the best for both the AA beneficiaries and the others, with consequent losses for society. Moreover, it increases the aversion toward the target groups of AA, and tensions among groups can increase.

Finally, another negative effect of AA corresponds to mismatching. It consists in admitting students to colleges that are too difficult for them and do not match their academic abilities. Under the mismatching hypothesis, AA often increases students' chance of dropping out of college, compromising their chances of graduating or pursuing their desired specialization. As a result, AA harms the intended beneficiaries (e.g., Amar & Sander, 2007). Mismatching has also been seen as a contributing factor to

reducing the achievement and completion of STEM degrees among specific populations (e.g., Hill, 2017).

Summary

Centuries have passed since AA was founded. However, forms of discrimination, persecution or exploitation of socio-economically disadvantaged groups persist. While AA originally consisted of policies and procedures aimed at eliminating discrimination at work against women and ethnic minorities, today discrimination also covers race, color, religion, sexual orientation, gender identity, or national origin. Consequently, the same target groups are no longer just women and ethnic minorities, but all those disadvantaged or minority groups who must be guaranteed a fair and equal opportunity to access to the socio-economic life of a country, as well as to the political ones.

In this sense, it is likely that the opposition between those for and against AA will continue to persist. On the other hand, the realization of a society in which fairness and merit are not opposed, but on the contrary, act in synergy for the growth of each person is a priority for the whole of human society.

This work outlines origins and definition of AA, reason for and against it, and provides examples of AA around the world.

African Integrated Maritime Strategy 2050: Challenges for Implementation

Ibukun Jacob Adewumi
African Marine Environment Sustainability
Initiative, Festac Lagos, Nigeria
World Ocean Council, Honolulu, HI, USA

Introductory Background

Globally, the roles played by ocean and seas in the Earth system are still not fully known, so is the information to adequately understand its impact on human activities remains nascent (Ehlers 2016). But from existing knowledge, marine ecosystems worldwide provide essential goods and services for the benefit of nature and mankind (Duarte 2000; Palumbi et al. 2012). However, these ecosystems are threatened by multiple

pressures and interactions, while there is a paucity of facts about the cumulative effects on maritime activities (Holon et al. 2018; Cormier et al. 2019). Hence, the range of interactions between anthropogenic and climatic pressures makes the management of the marine domain a complex task (McQuatters-Gollop 2012). The twenty-first-century ocean and climate change challenges have many faces, and there are different pathways to curtailing these challenges depending on the contexts. Among these pathways are marine management frameworks (e.g. Marine Spatial Planning, Integrated Coastal Zone Management) which utilize ecosystem-based management approach to increase social security, economic prosperity, and environmental protection –even beyond national boundaries and single-state stakeholders.

Cavallo et al. (2016) explain that the trans-boundary nature of the marine environment requires concerted actions among neighbouring countries to improve its quality in an effective way. Several initiatives have been taken worldwide to promote international coordination and integrated approach in marine management (Cavallo et al. 2019). Therefore, an integrated maritime strategy supporting such actions can help resolve issues in a polycentric governance context, especially where incomplete understanding and knowledge prevent potential win-win alternatives to emerge over the lose-lose conflictual current situation.

Africa is a “continental Island,” exhibiting uniqueness as it is flanked by a quadrilateral maritime belt (Rao 2014). With 54 countries, only 15 are landlocked states indicating that maritime economy is of great importance to the littoral states (see Fig. 1). Hence, increased disturbance of the marine ecosystem and safety have cumulative impacts on African coastal communities and their subsistence – a role that cannot be over-emphasized (Francis and Bryceson 2001; UNDP 2013; Engel 2014; IMS-UD/UNEP 2015). Nonetheless, just like in other climes, there is an increasing level of pressure and challenges at the regional and continental levels from both traditional and emerging maritime activities, exacerbated by climate change (Kebe 1990; FAO/UNEP 2016; Okafor-yarwood 2018; UNEP 2018);

African Integrated Maritime Strategy 2050: Challenges for Implementation, Fig. 1 Map of Africa showing coastal and landlocked countries (data source: Flanders Marine Institute 2019)

threatened by maritime security issues (Blank 2013; Hodgkinson 2013); and unstable and fragile political regimes (Rao 2014). While this warrants an integrated regional approach through a framework of action, African States are still unable to individually or collectively ensure a stable maritime order and governance in their maritime domain (Rao 2014). After all, maritime challenges in the region are almost homogenous, and common solution is needed if the continent is to successfully benefit from the potential of its maritime economy (Walker 2017).

Prior to 2014, there was invariably measly and inconsistent political and economic appreciation of the values of the ocean capital, and the management/governance of marine resource was predominantly sectoral. Besides, there was inadequate integration of common policy

framework at national, subregional, and regional levels for the delivery of collective actions to safeguard the regions oceans and seas (Engel 2014; Ukeje 2015; Walker 2015b; IMS-UD/ UNEP 2015). Africa countries recognized the need to move towards an integrated management and governance, adopting the 2050 Africa's Integrated Maritime Strategy (AIMS) in 2014. Upon the adoption of on the AIMS by the African Union Commission (AU) in 2014, a Strategic Plan of Actions was equally adopted – highlighting the major activities necessary to attaining the stated objectives, indicators of outputs, and responsible intuitions with responsibilities for the implementation of identified activities.

In 2019, the 2050 AIMS Plan of Action entered the second cycle (2019–2030) of its implementation, intending to fulfill the medium-term

objectives of “improving maritime workforce and research capacity, accentuating on programmes necessary to promote Research and Human resource development.” But scholars like Walker (2017) and Egede (2018) have argued that the implementation of the Plan of Action is principally failing due to lack of resources and expertise by the African Union (AU). However, at this stage of its supposed implementation, it is especially important to have a full picture of what the major impediments are, how to forestall them, and the necessary next steps for a successful implementation.

Just as the dynamics of strategy implementation in the marine sector is still in its infancy, this present chapter gives a general literature review on strategy implementation in other practice and knowledge field. With this understanding, salient issues emerging from the implementation of strategies in the marine domain are highlighted. Using the 2050 AIMS as a practical case study, impediments to its implementation as indicated by experts and scholars in the region were elucidated. Afterwards, the author amplified those factors which are more important to the 2050 AIMS’s implementation from his viewpoint. Finally, the chapter concludes by proposing recommendations to overcome these impediments for the current and future implementation phases of the 2050 AIMS. These recommendations can also be considered in the implementation of other Africa-wide instruments with similar reach and mandate.

The 2050 African’s Integrated Maritime Strategy (AIMS)

The African Union (AU) (OAU formally became the AU in 2002), formerly the Organisation of Africa Unity (OAU), was established in 1963, with the Secretariat headquartered in Addis Ababa. The AU, acceding to the OAU Charter of 1963 (OAU 1963), and pursuing the objectives enshrined in the 2000 Constitutive Act (AU 2000), purposes to promote and coordinate efforts of its Member States toward an Africa that is *united and integrated; imbued with the ideals of justice and peace; inter-dependent and robust; underpinned by political, economic, social, and cultural integration; committed to sustainable*

development; and devoted to ensuring the progress and prosperity of its citizens. Among the important tools used to express and galvanize these collective commitments is the development of policy documents that articulate the commitments, roles, and responsibilities of the Member States and the Secretariat toward goals and issues.

Out of a body of Africa-wide marine-related documents, the 2050 AIMS is the overarching framework which all member states are expected to follow (IMS-UD/UNEP 2015; Walker 2015a), to ensure complementarity among objectives and avoid overlaps in the path to sustainable wealth creation and maritime safety. Adopted in 2014, this ambitious strategy serves as the overarching framework for Africa to confront several of its maritime challenges, beyond a counter-piracy agenda. It intends to accelerate wealth creation and maritime safety sustainably by achieving four aims and 12 strategic objectives (Fig. 2).

Also adopted alongside the 2050 AIMS in 2014 was its Plan of Action to operationalize the strategy over the 2013-2050 period. Both the 2050 AIMS and the Plan of Action were innovative in several ways. First, they called for intersectoral action based on seven strategic areas that have a crosscutting impact on a range of priority maritime issues the continent is confronted with. For each strategic area captured in the Plan of Action, there were clear objectives, indicators, and recommended actions on the interagency, regional, and subregional. In addition to the 11 strategic programs, the Plan of Action proposed 21 objective goals, with 61 action target and 65 measures of outputs to help quantify and monitor the 2050 AIMS’s impact on the regional and country levels.

It is to be noted that the possibility of establishing new institutions and structures has been forecasted in the Action Plan, including extended focus on human capacity development for maritime governance (AU 2012). However, issues bothering on the financial requirements and implication to actualize the intention enshrined in the action plan were not documented either as at when the AIMS was adopted or till date.

Implementing Strategies Vis-à-Vis Marine Strategies

The definitions to what a strategy really is has always been given selective attention (Hax and Majluf 1988), and based on diversity of perspectives (Noble 1999). But to put it simple and straight, strategy is about success (Foundation of Strategy, n.d.). It recognizes the existing state of affairs, provides a vision for what the future should look like, and devises a plan of action for how to get from the present to the future (ACSS 2016). However, the bane of strategy is implementation, the de facto success rate of intended

strategies (Raps 2005). Therefore, an assessment of strategy implementation processes becomes crucial for practitioners and researchers alike in order to conduct and evaluate different implementation processes (Thompson et al. 2007). But at least, there are pieces of literatures in the strategy formulation and implementation field that have explored these dynamics. The 1980s show a rise in the study of strategy implementation. Waterman et al. (1980) proposed one of the earliest known work in this regard, putting forward the McKinsey's 7-S framework which identified seven implementation factors consisting of strategy, structure, system, style, staff, skills, and

subordinate goal. Jiang and Carpenter (2013) referenced several other studies such as Stonich, (1982), Hrebiniak and Joyce (1984), Galbraith and Kazanjian (1986), and Reed and Buckley (1988) who have also presented similar implementation factors adding to Waterman's voice. However, these earlier works were deemed not enough on the ground that they merely referred to individual factors, and neither did they provide explanation about their interrelationship nor empirically tested (Kazmi 2008).

Though Okumus (2001) reported that studies in the strategic management field had revealed the lack of knowledge on strategy implementation, more research is essential. This perhaps is also due to the lack of a cohesive body of existing implementation research (Noble 1999). After a critical review of previous frameworks, Okumus (2001) came up with ten key variables for strategy implementation: strategy formulation, environmental uncertainty, organizational structure, culture, operational planning, communication, resource allocation, people, control, and outcome. However, contrary to Kazmi (2008) critique of earlier works failing to explain the interrelationship between the factors, Oskooee (2017) explains that these factors are so close and often overlap to the extent that prioritizing them becomes difficult.

To deal with this unprecedented level of change in today's competitive, dynamic, and unpredictable world, 15 years after Okumus (2001) revealed the dearth of studies on strategy implementation, Katamei, Omwono, and Wanza (2015) disclosed that a lot of thoughts have been focused on strategy implementation. The complexity and dynamism are evenly largely observed also in today's marine space. But one would wonder why there has not been significant study shedding light in the maritime field, despite indication by experts and scholars to the difficulties in the implementation of maritime strategies (McQuatters-Gollop 2012; Walker 2015b; Cavallo et al. 2016, 2019). Most research in this area either concentrates on commercial organizations or programs of global funders and development partners with little or no attention paid to the challenges encountered in the process of implementing maritime strategies. Whereas,

effective implementation of strategy is a key factor to achieve strategic success (Oskooee 2017). This, in turn, reveals that focus also needs to be centered on the issue of strategy implementation in the marine domain.

In the marine/maritime field, few studies have drawn attention to the difficulty in implementing strategies directed at achieving sustainability either sectorally (Garcia and Prouzet 2009; McQuatters-Gollop 2012; Fulton et al. 2014) or holistically (Walker 2015b; Egede 2018; Cavallo et al. 2016, 2019). This challenge comes from the entire spectrum of the strategy itself, from its formulation to its review process. McQuatters-Gollop (2012) researched on the challenges for implementing the European Marine Strategy Framework Directive (MSFD) in a climate of macroecological change. Recently, Cavallo et al. (2019) reviewed the impediments to the implementation of MSDF with particular focus on challenges related to transboundary cooperation and policy integration. After identifying the salient present and future challenges (Table 1), based on Newton and Elliott (2016), they were categorized as either "bottlenecks" (the easily solved), "show-stoppers" (would require more effort to solved), and "train-wrecks" (most difficult to stop and discovered). After assessing the implementation of the 2050 AIMS, Walker (2015) concluded that its implementation is the most difficult part, as key activities in the plan of action have not yet been undertaken.

Challenges of Implementing the 2050 AIMS: Experts' Perspective

The Blue Economy has been made cardinal to the vision of AIMS (Walker 2015b; Egede, 2019; Hussain 2019). More so, its importance is vivid in many high-level policy documents such as the Lome Charter, Agenda 2063, etc. The AU's 387th Peace and Security Council final communiqué in 2013 expressly identified the Blue Economy as the "new frontline of Africa's renaissance." However, scholars and reports have faulted the AIMS, arguing that the strategic importance the AU accorded to the Blue Economy would be (has been) problematic to its implementation under its current operations. Walker (2017) identified three deficits to this effect:

African Integrated Maritime Strategy 2050: Challenges for Implementation, Table 1 Examples of “bottlenecks,” “showstoppers,” and “train-wrecks” in marine management (Cavallo et al. 2019)

Bottlenecks	Showstoppers	Train-wrecks
• Insufficient monitoring budget • Lack of (shared) targets [2.3, 2.4] • Decision on indicator aggregating methods • Multiple stakeholder fora [2.6] • Lack of data (ecological, social, and economic) [2.1, 2.4, 2.6, 2.7] • Excessive and redundant advice documents [2.1] • Lack of harmonized and generic indicators [2.2, 2.4, 2.7]	• Complex regulation [2.4, 2.5] • Complex reporting [2.1, 2.4] • Lack of experts with multidisciplinary background • Overlapping designation • Sectoral management (e.g., separate management for fisheries, energy, nature conservation) [2.5, 2.6] • Poor coordination among national agencies • Different economic prerogative (i.e. blue growth with precedence over GES) [2.2, 2.6] • Lack of use of technologies • Short timescale	• Resistance to collaborate • Lack of dedicated funding • Legal challenges • Political will • Unwillingness to adopt joint aims/vision • Inflexible planning system • Sociocultural conflict

The numbers in brackets in column 1 and 2 refer to the sections in the main text where challenges related to transboundary cooperation and policy integration are discussed. Illustrations of train-wrecks are evaluated in the Discussion section.

1. The need to define the term “Blue Economy,” emphasizing that a major challenge to maritime stakeholders is that the AIMS did not do justice to what the term means both legally and in practice. This argument is apt as ideally, maritime policies for Africa should be developed as a process around a defined Blue Economy and maritime security (Swanepoel 2017).
 2. The inability to establish a dedicated standalone maritime entity within the AU, with the mandate to coordinate and steer action toward accomplishing the 2050 AIMS’s objectives. Even though this need has been recommended by a 2009 resolution of the Third Sea Power for Africa symposium in Cape Town (Wingrin 2009), established within 2050 AIMS itself, and supported by African maritime ministers in the Addis Ababa Declaration of 2012 which endorsed 2050 AIMS.
 3. The inefficiency of the 2050 AIMS Strategic Task Force (STF). The STF has incessantly failed to convene consistent meetings critical to the implementation of the 2050 AIMS as mandated by the 2014 Malabo Declaration (AU. 2014).
- challenging — emphasizing that achieving *coherence* with the different wide-ranging maritime issues it tends to address is difficult. This coherence, he said, would only be achieved if these three core issues are put in the front burner:
- (a) *Effective coordination*. Just like Walker (2017), he advocated for a prominent department in the AU with clear mandate, like the UN Department of Ocean Affairs (DOALOS) that would coordinate the 2050 AIM Strategy and the various aspects of the African Blue Economy.
 - (b) *Information flow*. To keep the implementation of the 2050 AIM on the front agenda of the AU assembly, a reporting mechanism (like the United Nations Secretary-General’s annual oceans report to the General Assembly) should be dedicated to communicating annual reports on the progress made in the implementation of the strategy and the Lomé Charter, presented to the Assembly by the AUC Chairperson, and posted on the AU website.
 - (c) *Nexus approach*. With the 2050 AIMS acknowledging the inter-connectivity of maritime issues, paying cognizance to the interaction and interdependence (the nexus) of the different issues, and communicating them accordingly would aid its implementation.
- Egede (2018) believes that the 2050 AIMS is seemingly complex, and its implementation would be

Challenges of Implementing the 2050 AIMS: Author's Perspective

Blue Economy Is a Contested Concept (Never Done Before)

The 2050 AIMS anchors itself on the precepts of the Blue Economy. However, arguments have ensued about what the “Oceans Economy,” “Blue Economy,” or “Blue Growth” concept really means at global, regional, and national levels. Specialists and researchers have presented several definitions. The Economist Intelligence Unit believes that “A sustainable ocean economy emerges when economic activity is in balance with the long term capacity of ocean ecosystems to support this activity and remain resilient and healthy” (Goddard 2015). The World Bank in a report on “The Potential of the Blue Economy: Increasing Long-Term Benefits of the Sustainable Use of Marine Resources for Small Island Developing States and Coastal Least Developed Countries,” implied Blue Economy as: “the range of economic sectors and related policies that together determine whether the use of oceanic resources is sustainable.” These definitions and others remain contested, and the need for a clear meaning remains active, even as it is related to its usage in the 2050 AIMS (Walker 2015b; Egede 2018). Though as variant as the available definitions of the concept might be, the truth is that there is no unique definition of the concept, as it is only caught up in language schematics based on context and the interpreter.

Fred W. Riggs in his 1979 article “The importance of concepts: some considerations on how they might be designated less ambiguously” pointed to the fact that the use of different technical words, terms, and nomenclatures in social science also have a wide variety of connotations in everyday usage. He referred “concept” as a way of distinguishing between the various meanings of word (Riggs 1979). Bassey (2000) quoting Eugen Wüster (1974) also lends a voice stating that, the starting point of all terminology work is the concept and indicates why terminologists speak about concepts while linguists speak about meaning. Anyway, in relevance to this study, what is certain is the inevitable effect of the meaning on the Blue

Economy concept on the strategy implementation, because it affects the ways of perceiving solutions to maritime issues and even thinking about them. Unfortunately, even just for the sake of it, the 2050 AIMS has not provided an “African” version of what Blue Economy “should” mean. Swanepoel (2017) believes that immediately this concept is better understood, and legally defined, African countries can continue their work to incorporate Blue Economy into national maritime policies.

Another connected factor here impeding the implementation of the 2050 AIMS is the *shock of something new and fresh*. Due to the complexity of what the 2050 AIMS professes, some AU Member States are still resistant to change, and still prefers the status quo of sectoral management approach. Resistance to change according to Hrebiniak (2013) and David (2011) is often the single greatest obstacle to effective implementation of strategy. Most African countries even though bounded by the sea, and fully aware of the myriads of ocean challenges confronting them, still perceive that it would be foolhardy to go into the integrated ocean governance scheme as preached by the 2050 AIMS. However, the 2050 AIMS has not provided a kind of contingency plan or alternative scenario that could accelerate buy-in at national level.

Structures to Achieve Coordination and Coherence at National, Regional, and AU Levels Not Adequate

Just as coordination at international level is essential for the implementation of environmental policies aimed at reducing the consequences of constant interaction between nature and uses such as shipping and fishing (Cavallo et al. 2016), the success of Africa's maritime future lies in coordinated, integrated actions and policies for combined and joint projects (Walker 2019). The growing importance of maritime activities such as fisheries, shipping, resource extraction, tourism, and offshore renewable energy across Africa's seas requires strong political coordination among countries that share the same marine area to ensure more sustainable management of the marine environment. This is also relevant as

the ecosystem approach expressly professed by the 2050 AIMS requires cross-cutting implementation (no silos). However, the structure to do so is technically absent, or grossly inadequate (IMS-UD/UNEP 2015), even though the 2050 AIMS presented the development of new institutions and structures as part of its objectives. For example, the proposed Special Task Force (S2TF) saddled with the responsibility to oversee the realization of the proposed Combined Exclusive Maritime Zone of Africa (CEMZA) is yet to be put in place. Even the (New Partnership for Africa's Development) NEPAD Planning and Coordinating Agency (NPCA) whose mandate within the AU is to coordinate the implementation of AU's programs of action have not attempted forging coherence and coordination of the targets embodied by the 2050 AIMS. Whereas, having structure proportional to strategy is a critical factor in the strategy implementation (Oskooee 2017). Also, the definition of how to create coordination is not visible within the 2050 AIMS and its Plan of Action – as it does not adequately define whether existing or proposed implementing organizations should be dependent or run more independently; if coordination should be done in a coalition or not; and even if the organizations responsibilities should requires a high level of coordination or not.

Absence of Adequate Institutional Power and Information Sharing Capacity

Power had been identified as a key factor for the successful implementation of the strategy (Hrebiniak 2013). Even though power can have negative performance in strategy implementation, it mostly facilitates the development and implementation of strategy (Oskooee 2017). The weight of the 2050 AIMS exceeds the organizational value and power structure of the 2050 AIM Strategy Task Force (STF) set up in June 2011, which marks why it has been said to record more failures than points. Given the glaring failure of the STF, it is time for the AU to adjust its structure to suit the needs of the 2050 AIMS by urgently putting in place a better empowered organizational unit, where there would be a proper balance between centralization and decentralization of decision-making in favor of the correct

implementation of the 2050 AIMS. Hence, corroborating earlier arguments put forward by Walker (2017) and Egede (2018) expressing that the responsibility to coordinate and implement the 2050 AIMS should go beyond the STF. However, contrary to Walker and Egede's idea of a standalone department within the AU, and seeing the inefficiency of the NPCA as an agency of the AU, a counterpart technical commission (African Blue Economy Commission) just like the African Energy Commission or body such as the African Union-Inter Africa Bureau for Animal Resources (AU-IBAR) be created, as commissions are more independent and with statutory legal power and competency. This would also help in delegating responsibilities more efficiently (whether on board, Working Groups, Advisory Groups, etc.) and activate the process of coordination.

Checking through different repositories, hardly could one find documents relating to the progress of implementing the 2050 AIMS. This to a large extent stems from the inadequate capacity of the STF. A recognized impediment to implementation of the strategy and (organizational learning) is poor communication (Beer and Eisenstat 2000). By establishing a dedicated organization saddled with the responsibilities to coordinate and implement the 2050 AIMS, the efficiency of designing a functional plan or strategy (e.g., as suggested by Egede, 2018) for determining how information sharing and knowledge transfer will be attained surfaces.

Potential Implementation Burden Rising from Disproportionate Operational Planning

Robbins and Coulte in their 2012 classics *Management* alluded that operational planning is to choose the means to achieve *short-term goals* (Robbins and Coulter 2002). The 2050 AIMS Plan of Action have 11 strategic programs, 21 objectives goals, and 61 target actions which would not be said to be too cumbersome or superfluous of such. However, apart from the fact that preconditions (such as proper coordination and presence of capable implementing organizations, timely availability of funds, effective monitoring) to implement the 2050 AIMS are simply not available or inadequate, the

operational programs presented to achieve the 2050 AIMS are mostly short term, while the 2050 AIMS has a long-term horizon. And to implement a strategy, the designing of appropriate programs is necessary (Hrebiniak 2013). Perhaps Abah (2017) is right by saying that “Africa’s problem is planning, not implementation!”. His statement validates Oskooee’s (2017) assertion that even if strategies are formulated properly, it does not guarantee successful implementation; hence, a successful implementation of the strategy should be planned. As the marine ecosystems are interconnected both vertically and horizontally beyond legal boundary, so are the various maritime activities, uses – requiring regional and global responses. The interconnectedness of maritime issues and its relationship with the 2050 AIMS has been elucidated by Egede (2018). Hence, programs with a long-term vision taking into consideration the interwoven relationship between different maritime sectors and uses should have been proposed. This deficiency in the 2050 AIMS regarding operation plan also springs up the issue of funding. Operation plan ensures successful implementation of action and monitoring, and at the same time necessitates the preparation of project funds and identification of clear sources of funds (WWF 2007). However, neither the 2050 AIMS nor its Plan of Action contains any information on funding to implement stated objectives. This would once again reinforce the ongoing argument that funding is one of the reasons why projects fail in Africa (Ika and Saint-Macary 2014; Marabuka 2013).

Lack of Knowledge and Data

The 2050 AIMS has listed Marine Spatial Planning (MSP) as one of the instruments to ensure coordinated and coherence ocean governance in Africa. However, MSP approach among others, leverages on evidence-based, verifiable data and stakeholders participation for its short- and long-term operation and process (Blæsberg et al. 2009; IOC-UNESCO 2009; Gunton et al. 2010; Gimpel et al. 2015; Siddiki and Goel 2015). Interestingly, the 2050 AIMS acknowledge that a robust and precise data is needed for any analysis aimed at

informing policy makers, and also admit that such data were limited or nonexistent. Throughout the document, need for, and the intention to fast track data collection, storage, and sharing was resounding. It proposed:

1. Including pooling of knowledge into an African marine data center
2. Creating a maritime database generation and maritime information exchange network
3. Data gathering and statistical information, nodal point for cross-sector maritime

Till date, unfortunately, the reality remains that there are no such data or facilities available, and this seem not to be a new experience in the region. The lack of data has been generally blamed for Africa’s inability to adequately cater for its conservation needs (Kudom-Agyemang 2019). The complexity of ensuring the implementation of 2050 AIMS with its myriads of actors and drivers make the need for data increasingly desirable. The failure to address this would create a vicious cycle of challenges inhibiting the implementation of the strategy and the realization of evidence-based, empirically backed marine policy options in Africa. For example, assessing the implementation of the 2050 AIMS at regional, subregional, and country level will be challenged due to lack of data and information sharing channels. Of course, this would be aggravated by low institutional capacities across, and glassy communication between sectors, institutions, and stakeholders. These vicious cycles thus will affect existing (if any) mechanisms put in place to ensure stakeholders participation in the implementation process.

Recommendation and Conclusion

Conclusion

Several key conclusions can be drawn from the study which has implications for the implementation of the 2050 AIMS and other documents of its kind both in Africa and in other climes. First, issues related to strategy implementation cuts across different research and practice domain,

where even the business and corporate sectors are still grappling with implementation challenges. The literature review aspect of this study also reveals that a significant amount of literature about strategy implementation is out there and that a close analysis of their findings indicates that the variables identified to be impediments to implementing strategies in the business, management, and corporate world are similar and inter-related to the factors the author deduces as impediments to implementing the 2050 AIMS. Hence, those in charge of evaluating and reviewing the implementation of marine strategies would benefit from the range of resources already available that can be compared. The literature review also espoused that there are few papers and experts' opinions on maritime strategy implementation, and their conclusion about the challenges is similar and overlapping.

Based on authors' experience and perception of the 2050 AIMS, those factors limiting the implementation of the 2050 AIMS are products of the process, tactical and operational deficiency of the strategy. They include issues with the novelty of the concept which the strategy is predicated, inadequate mechanism for cooperation, and misnaming critical programs and targets of the Plan of Action at regional and national level. Issues related to low political buy-in, and competent institutions to coordinate and champion the implementation of the strategy were also identified. Tactically, the operation planning of programs and lack of budgeting provisions, plus the complete absence of data on progress of implementation, also inhibits the implementation of the strategy.

Therefore, it can be claimed that the process of formulating the 2050 AIMS and its Plan of Action, right from the design to implementation phase have largely contributed to the low success in implementing the strategy. It should also be noted that internal context plays a key role in achieving the goals and objectives of maritime strategies, and focusing on the implementation process alone and ignoring the wider context does not provide a clear and holistic picture of the implementation process and its challenges.

Recommendations

Blue Economy is contested concept (never done before)

The 2050 AIMS and its Plan of Action are due for review considering the loopholes in its logic and conception, and this should be carried out periodically afterward. Perhaps, the time is now for the "definitional" burden of the Blue Economy be addressed in a reviewed version of the 2050 AIMS. However, we cannot shy away from the fact that concept, no matter how well defined they might be, would still be subjected to contests. From the legal parlance of "essentially contested concepts," Gallie (1955) already gave us an inkling that a particular use of any concept [...] is liable to be contested for reasons they usually carry with them an assumption [...]. Along this reasoning of an essentially contested concept, we can then borrow a leaf from the grand solution proposed by Waldron (2002) and supported by Collier, Hidalgo, and Maciuceanu (2006) emplacing that, "the rule of law is the solution to a problem we are not sure how to solve." Therefore, either at national, subregional, or regional level, a legislation which clearly defines the Blue Economy concept should be passed into law. This also implies the need to make the 2050 AIMS legally binding, where states can transpose it into their national legal structure.

Structures to achieve coordination and coherence at national, regional, and AU levels not adequate

Successful implementation of the 2050 AIMS would require strengthening institutions and intensifying efforts toward getting buy-in from governments at national levels. As most countries in Africa already have a national vision and the policy basis for sustainable development, some of them are already thinking of how to incorporate Blue Economy thinking into their national policy (e.g., Nigeria, Kenya, Benin), while some especially the Small Island States are way beyond others. To achieve more coherence and coordination, a cross-cutting logic needs to be reflected in the 2050 AIMS Plan of Action. Few things must be put in place, including:

- (a) The 2050 AIMS must be legally binding, compelling states to transpose it into their national law just like the EU Marine Strategy Framework Directive.
- (b) Since the AU is currently the main coordination organ for facilitating the implementation the 2050 AIMS Plan of Action, the principle of subsidiarity should be followed in order to galvanize a lot of political will and commitment to effect change at national level. (The principle of subsidiarity indicates that any policy is better achieved at the most immediate level closer to issues (in this case the states).)
- (c) As the Plan of Action has not provided any indication of how coherence and mainstreaming of the 2050 AIMS would be mapped at the regional/national level, a detailed legal guidance on the mainstreaming of the 2050 AIMS should be developed.

Absence of adequate institutional power and information sharing capacity

Bridging strategy implementation skills gap is critical, as successful strategy implementation depends on people taking the right actions (Speculand 2014). Also, improving the capacity to look ahead is critical as the process of progressive implementation will require capacity to anticipate the potential consequences (Garcia and Prouzet 2009). Therefore, by establishing a dedicated Commission in charge of coordinating and implementing the 2050 AIMS, the power of institutional influence and credibility will facilitate capacity development, as a well-structured institution uniquely positioned to drive change.

Additionally, it is understandable that the process of establishing a standalone institution as recommended in section “[Absence of Adequate Institutional Power and Information Sharing Capacity](#)” might take some time. A tentative arrangement could be made whereby the AU will constitute a thematic cross-sectoral regional Blue Economy Committee that will work in tandem with the STF, and chaired by regional coordinator (for example, selected among the Ministers of Environment, Transportation, Ocean Economy, etc. in each region) who will work

to champion and increase support for the 2050 AIMS at the national level.

Potential implementation burden rising from disproportionate operational planning

Moving past the implementation burden created by faulty operational planning of project will require a review of the 2050 AIMS Plan of Action. A project is successful when it has met needs of stakeholders. Therefore, during this review process, it is important to allow the needs of stakeholders to guide the identification and design of programs and cooperate to determine the indicators that would be used to evaluate their implementation.

To every action, there must be a reaction. This saying also applies to marine policy implementation, as the policy process creates a demand for action, which in turn requires financing (IMS-UD/ UNEP 2015). Therefore, at this stage, a general assessment of financial requirement of implementing the 2050 AIMS at least over the medium-term implementation period should be carried out. For the expected lifetime of the 2050 AIMS, high-level (not too detailed) financial estimates must be prepared showing current and potential sources of funds, the estimated cost of actions and programs presented to implement the strategy at different stages, the monitoring activities, as well as any other resources gap. IMS-UD/ UNEP (2015) has succinctly provided a number of recommendations that the handlers on the 2050 AIMS must consider to scale the funding hurdles, which includes adopting innovative approaches such as the Blue Bond and Payment for Ecosystem Services (PES), establish continental-wide special fund for ocean governance, etc.

Lack of knowledge and data

Though at the initial stage of strategy implementation, data seem to be very scarce. However, the 2050 AIMS is not in its second implementation cycle, therefore, a semblance of data to champion should be available. Developing a data strategy can help to overcome the challenges and bring efficiency to the implementation process (Attaran and Attaran 2018). The solution here is to have a 2050 AIMS data strategy that articulates how both input and output data will enable and inspire the strategy. This will include an indication

of how data will be collected, managed, shared, and used. Relevant input and output data from similar Africa-wide strategy (e.g., the African Development Bank Strategy for agricultural Transformation in Africa 2016–2025, the AU Continental Agribusiness Strategy Driving Africa's Growth, and the African Union Strategy on Climate Change) should be retrieved and documented to improve buy-ins for the 2050 AIMS and to enhance coherence in its implementation. For example, in the implementation of the European Marine Strategy Framework Directive (MSFD), the use of existing data, methodologies, and targets from related environmental policies corresponds to the higher levels of coherence among countries, while a limited use of such policies produces less coherence (Cavallo et al. 2016).

Age-Based Discrimination

► Ageism

Ageism

Kristijan Krkač
Zagreb School of Economics and Management,
Zagreb, Croatia

Synonyms

[Age-based discrimination](#)

Definition

The shortest, the most common, and on the face of it the clearest English dictionary description of “ageism” says that “it is the prejudice toward, stereotyping or discrimination of a person or group of people because of their age” (Low and Ang 2013). However, as it is often the case, clear, short, and elegant definitions hide and imply a lot most of which isn't neither clear nor short, and in most cases quite unfashionable. Two, among many defects of such descriptions, are that neither by being too universal they do not apply to actual practice that a description supposes to describe, nor by being too clear criteria have acceptably short list of standard exceptions.

Ageism

The fact is that humans as any other developed biological species with sexual reproduction

systems are getting older, becoming old, and die (opposite to, e.g., some simple organisms that are virtually immortal). Evolutionary, biologically, and gerontologically speaking, this fact isn't explained yet. It is also the fact that the world population is aging more rapidly than ever before, meaning that there is the constant growth in number and proportion of older people in the world's population.

Further on, aging is becoming extremely relevant medically speaking since it is among the greatest risk factors for most diseases. These facts further on immensely determine changes in legal, economic, political, social, and cultural aspects of the human species. Last but not the least, it is also a fact that, in part due to these facts, the phenomenon of ageism as a negative prejudice, stereotype, and discrimination of an individual or a group because their age exists and is becoming more and more relevant. On the margin of causes of ageism, there is also the so-called the cult of the youth which doesn't just deny ageism but tends to deny obvious facts about aging, sometimes conceiving it as a kind of social construct. (Neiman 2014).

In what follows, ageism and aging will be described, ageism theories will be listed, and ageism at workplace will be explicated in detail as the most frequent and the important type of ageism in its positive and negative, implicit and explicit types, and in its economic, business, legal, sustainable, and moral aspects so that the complexity of the issue and related practices can be viewed in detail and applied in other situations *ceteris paribus*. The reason for this example is given by the facts about humanity which says that the "world human population in ageing rapidly" (United Nations, Department of Economic and Social Affairs, Population Division) (2015). World Population Ageing 2015 (ST/ESA/SER.A/390), and therefore the workforce, is getting older as well which leads to new demands in workforce treatment and overall approach to it in social, cultural, economic, legal, and moral aspects.

Let us begin with first level of complexity concerning the elements of mentioned definition. "A stereotype is any thought widely adopted

about specific types of individuals or certain ways of behaving intended to represent the entire group of those individuals or behaviors as a whole" (McGarty et al. 2002). The first problem is that these thoughts or beliefs may or may not accurately reflect reality (Judd and Park 1993). Now, there is obvious tension between a common misinterpretation of stereotype which says that it doesn't reflect reality and its original meaning which says that it is any "solid impression" (*stereos + typos*) and it was invented for a quality of a copy in the printing trade. Let us stop here and move to the second concept.

Stereotype is similar to prejudice, and discrimination, but it differs from them in a way that it emphasizes cognitive dimension, while prejudice emphasizes emotional, and discrimination practical dimensions. Therefore, a stereotype can be only incorrect so far as an impression isn't solid, but as such it can be wrong if it leads one toward, justifies, or causes some negative prejudice (given that there are positive prejudice as well) and surely if these two lead to discrimination. Discrimination is any disadvantageous or prejudicial consideration or a treatment of an individual based solely on their belonging to a particular category (social, ethnic, racial, etc.).

Basically, to discriminate is to consider to act or to act indirectly or directly intolerantly. Finally, A tolerates B if and only if: A disagrees with what is B doing or intends to do, A can prevent B in doing, and A doesn't prevent B. Consequently, if A is preventing B in an action because A disagrees with the action in question, B is acting intolerantly toward B. In a quite vivid example, A can be a manager in a company who disagrees that B, who is an older employee, continues to work, no matter if the relevant international documents, national legal regulations, and company's policies allow her or him to continue to work. A can dismiss B only because B is older employee, and A disagrees that older employees should work for the company, since, as A thinks, "It is a dynamic environment composed of young and creative people." If this is the case, it is an obvious situation of intolerance, discrimination, prejudice, and stereotyping of an employee based solely on her or his age and therefore the case of ageism.

Last but not least, “ageism” in its core rests on a biological fact about developed living beings, humans included, which correctly says that people age, or that they undergo the normal stage in life called “aging” or “becoming old.” This biological fact is in a way considered negatively, for instance, in “politically correct” talk which doesn’t tolerate expressions such as “old woman” or “old worker,” while suggesting that “a senior citizen” or “a senior employee” is the right non-discriminating, non-prejudicial, and non-stereotypical way of talking, considering, and acting toward old people or anti-ageism policy.

This short definition of ageism (Butler 1969) no matter how narrow it is, i.e., considering only negative action toward old people qua old people, shows these and many other flaws. Some contemporary analyses of aging try to broaden the scope of it by saying that ageism is not directed toward old people as old people, but toward young people as well, since they can be subjects of ageism as well (Bytheway 2005), and some try to broaden the scope to any age group at all (Palmore 1999). These developments surely help understanding ageism more fully, especially if it is detected and fought against with various policies in different demographical situations; however, they do not supply effective description that can determine our practice against it. Much of problems of ageism, previous to all other phenomena, rest on its unclear relation to biological fact of aging, and much of them rest on the implicit practice of ageism (since explicit and direct ageism is not common due to various cultural, political, and even legal constraints).

Aging

One among many obvious situations in which the presented description of ageism doesn’t help, much is a situation in which “being old,” “being young,” or for that matter “being of any age” whatsoever is in fact an advantage, and therefore ageism or even better aging (sometimes positively referred to as “seniority”) seems to be a correct

description, and a possible positive prejudicial and positive discriminating action can be justified and morally good under some further conditions. For various activities, professions, lines of work, and hobbies, “being of a particular age” is not just an advantage, but previous to that a necessary condition of an activity. This is obvious for many activities for which “being of a particular age” is biologically important, e.g., for a development of a particular physical capabilities in people, say physical speed by running certain age is necessary. Namely, if this particular capability isn’t developed in a particular age, the capability will remain undeveloped or at least underdeveloped.

Furthermore, for particular activities, an amount of experience, defined by years of practice and level of expertise and excellence, is a clear precondition; therefore, “being of a particular age” is a precondition of engaging in an activity, e.g., being any kind of a coach, trainer, educator, teacher, mentor, or similar, say in sports, at a workplace, in private life, etc. So the issue here isn’t just about positive and negative ageism, but previous to that the issue is about relating ageism to aging in both positive and negative ways and to differ between them at least for practical purposes.

Being old or being young doesn’t mean that one is automatically more suitable for an activity given the fact that they are being in the right age for an activity, or having a certain amount of experience doesn’t necessarily leads to suitability of acting. However, clearly stating that an individual or a group is at the particular age for a particular activity or a practice has nothing to do with ageism, and it is connected to age solely. So it is important to be able to talk and act in respect of an age of an individual or a group without being negatively prejudicial, stereotyping, or discriminating in terms of ageism. Between what ought to be done (i.e., how to escape negative ageism), and what is the fact (i.e., use of age and aging properly), there are some theories about ageism which try to explain or at least explicate why this phenomenon occurs in societies and cultures.

Biologically and evolutionary speaking, aging emerged when the evolution of sexual

reproduction occurred. Before that, starting approximately at 3.7 billion years ago, there were singled-cell organism on Earth that reproduced by fissioning into daughter cells. Sexual reproduction brought change, and humans are no exception (this should not be mixed with the fact that some cells even in humans have the potential for immortality). Aging is normal, and as such it normally occurs in any group or a population of humans. Biological causes of normal aging are still researched, and there are several competing models of it, like the model of damage which causes organ systems to fail and programmed aging model which says that there is a mechanism which causes aging. Prevention of aging on individual and organ systems level is one of the most researched topics in human biology and medical sciences. The social and economic issue especially rises if the group of older individuals is growing rapidly and becomes dominant group in a given population because the population on average is getting older.

The issue here is aging which is dominant in the dynamics of a population, i.e., increasing number of older people in it. This phenomenon leads to a new biological and demographical stratum, namely, dominance of a particular age group, and consequently different social stratification (the so-called age distribution or age composition). In other words, normal age distribution or age pyramid in a society is changed, i.e., stationary pyramid is changed to the model which is a mixture between expansive and constrictive pyramids because there is a high birth rate (and other causes like immigration of families with more than two babies) and in the same time this birth rate is overpowered by higher life expectancy. Consequently, absolute number of a population is rising, and also the number of older groups in it, and the median age is rising (e.g., in EU, North America, and Japan, it is above 42 years and rising in the period 1990–2020). This fact determines a lot in a society, from family, education, work, quality of life, and even leisure time.

The UN 2015 report “World Population Ageing,” based on global and precise data, claims that

aging is not just the fact, but perhaps one among the most important facts about humanity in the near future:

The world’s population is ageing: virtually every country in the world is experiencing growth in the number and proportion of older persons in their population. Population ageing—the increasing share of older persons in the population—is poised to become one of the most significant social transformations of the twenty-first century, with implications for nearly all sectors of society, including labour and financial markets, the demand for goods and services, such as housing, transportation and social protection, as well as family structures and intergenerational ties. Preparing for the economic and social shifts associated with an ageing population is thus essential to ensure progress in development, including towards the achievement of the goals outlined in the 2030 Agenda for Sustainable Development. (UN 2015)

Generally speaking, the most developed regions in the world are actually dying since there is growth of people of middle age combined with smaller number of children and greater number of old people. Such condition determines almost everything in such regions, from individual to social rules and customs, and from legal to economic activities and models. Old people in such populations become a dominant group, and consequently children and very old people are minorities. In that light, previously mentioned definition of ageism which broadens the concept from old people to young people makes perfect sense in such demographically structured populations. Ageism is a present phenomenon, and it is possible that it changes due to changes in the age distribution of a population which makes it quite interesting phenomenon in need for a new explanation and hence new models of ageism and policies of reducing ageism.

Ageism Types and Models

There are four ecosocial levels of analysis that can be applied to ageist manifestation in society. From a macro, meso, micro, and individual level, these ageist categories are structural, institutional, interpersonal, and embodied ageism.

N. Krieger offers some excellent and succinct definitions of structural, institutional, and interpersonal discrimination, which apply well to ageism (Krieger 1999).

E. Palmore claims that structural ageism, also known as “systemic ageism,” is the “totality of ways in which societies foster discrimination” against older adults. A subset of structural ageism, cultural ageism, encompasses ageist media messages, commentary, humor, and other cultural facets wherein ageist perspectives are accepted as de facto truths.

Institutional ageism, or “organizational ageism,” refers to “discriminatory policies or practices carried out by state or non-state institutions” that are detrimental to older adults. Interpersonal ageism or “institutional ageism” refers to “directly perceived discriminatory interactions between individuals” (Palmore 1999).

Although ageism is often direct, explicit, and efficient, new social, cultural, and political circumstances give rise to indirect and implicit ageism. There are no obvious stereotypes and prejudices toward any age group, not even direct discriminating practices, but they are obviously implicit and deeply rooted in societies. Implicit ageism shouldn’t be mixed with benevolent ageism which is directed, for instance, toward younger or older co-workers who are patronized or pitied, but explicit ageism is often hostile and direct.

Ageism at Workplace

A known joke says that an employer wanted one younger candidate with at least 20 years of experience and also one experienced candidate not older than 25 years of age. So a woman applied for both jobs, and she said to the interviewer that she is 25 years old, that she has 15 years of experience and a PhD and a DBA in accounting. The interviewer looks at her, thinks to himself, she is obviously more 30 years old, with no more than 10 years of experience tops, and without PhD or DBA, and he says to her: “Well, what you are saying is impossible.” She replied: “To say something which is impossible to these impossible

recruitment conditions was the only possible thing to do.” She got the job.

Contrary to the joke, many young people don’t get jobs because they are too inexperienced; many are poorly paid because they are the youngest and patronized in the workplace because they are inexperienced, and many efficient elderly workers are dismissed only because they are old. The previous joke doesn’t seem to be so comical anymore, more to that, it seems tragic, and it is a typical ironic and sarcastic response to typical rising ageism discrimination all around the world (only in some rare societies, older workers are taken as the crucial part of the workforce because their expertise, experience, and capability of passing knowledge to younger workers which is considered as of utmost importance for continuity and stability of a business).

As any other ageism, so is workplace ageism stereotyping, prejudicial, and discriminating attitude comprising cognitive, emotional, and proactive and practical elements toward employees of any age group. Given that the major group in a workforce is similar to the major group in age distribution in a society, the most frequent groups that will probably suffer ageism are younger and older employees. Some of ageism practices are in some countries allowed by different laws and sublegal rules and procedures, for instance, in a case of younger workers, these can result in unequal payment for an equal work, and similar can be the fact for older workers, especially women (therefore, ageism as the age discrimination is combined with the sexism and gender discrimination). In some countries, age discrimination is explicitly prohibited besides the fact that there are various regulations regulating equal employment opportunity.

Ageism here makes a strange relation to ageism as the normal age distribution in a population and workforce as well. Namely, ageism is quite irrational economic practice given that it is highly probable that strengths and opportunities generally override weaknesses and threats in younger and older groups of employees. For instance, energy, creativity, and easygoing features of younger employees and experience and capability of mentoring younger employees by seniors are

besides being economically rational, also quite natural for any group engaged in a line of work that doesn't have objective, e.g., psycho-physical age conditions.

Therefore, by being discriminating practice, ageism seems to be an irrational business practice as well, and as such bad for business. Nevertheless, the practice still goes on despite legal restrictions and being an irrational business behavior. For instance, in many EU countries, candidates of older age get approximately 50% less job interview invitations compared to those of younger age (Ahmed et al. 2012; Baert et al. 2015; Kautonen et al. 2015). Furthermore, mandatory or obligatory retirement age which exists in many countries and companies, as it was initially planned, doesn't create greater opportunities for younger candidates.

Since all age groups cannot be covered here, only old workers will be covered, and it is possible that facts, rules, practices, and policies apply to all other age groups of workers *ceteris paribus* (different estimation say that in developed countries, workforce of age 65 occupies 25% of the whole group and that the rapidly growing tendency is to rise to 1/3 in the near future (U.S. Department of Labor Bureau of Labor Statistics 2008)).

One should keep in mind that ageism of older workers in workplace overlaps with other types of discrimination in workplace on the one hand and with other types of ageism outside of a workplace, i.e., in private life, in local community, etc. This is relevant as far as some discriminating practices toward older workers are simple continuation of discrimination practices toward older persons in society and private life.

Practical policies try to restrict ageism at workplace, besides following legal constraints that apply more strictly, but also they may be more proactive, meaning not just protecting older employees from ageism, but also creating age-friendly workplace environment. Such policies present a great problem for practitioners of business culture (objectively) and organizational climate (intersubjectively), namely, for human resources (HR) departments in companies. Among these policies, flexible work load

and working hours can contribute substantially to creating old age-friendly workplace environment.

Such policies do not present extra cost for companies and may gain extra profit given that for a series of professions, there is no proof that older workers will be less efficient simply because they are older, rather for a series of other causes among which the very ageism discrimination may play significant role in lowering their motivation (in a way it seems true that "Old is the new Young" as claimed by a Canadian post-punk band "No means no").

Therefore, it seems rational, efficient, by all means legal, and perhaps morally correct as well to avoid any form of negative ageism in the workplace. Formally speaking, this means avoiding it during recruitment, setting of the workplace terms and conditions, and dismissal. Points of recruitment and dismissal are often covered by media and popular texts, but they are in terms of quality and quantity almost irrelevant compared to ageism in view of the workplace terms and conditions.

Ageism in employment can contain advertising for someone to join a young team, not interviewing someone because they are too young or too old to, not employing younger workers because it's assumed that they'll quickly move on, not employing older workers because it's assumed that they'll soon retire, not providing training opportunities for young or mature workers because it is too expensive given the probable benefits, limiting their job responsibilities and duties, forcing someone to retire, because of their age, many forms of mobbing of young employees by older and vice versa, or by superiors, etc.

So ageism can be "horizontal," i.e., among co-workers, and "vertical," i.e., between managers and workers. It can be implicit, i.e., hidden within actual practices covered up by formal alignment with the legal requirements and best practices of avoiding ageism, and it can be explicit.

As said, various policies can successfully minimize ageism in a company, especially in the workplace and that for the benefit of all parties

included, namely, the owners, management, workers, company's image in a community, society, and especially among buyers and regular customers, etc. Anti-ageism policies aren't implemented just by following laws and other regulations and best practices, but also by implementing pro-age policies in all cases in which ageism is going on and needs to be reduced for the good of all.

Summary

There are facts about aging and fact about ageism. The origins and causes of both phenomena remain unknown which leads to some problems in dealing with them. On the other hand, what isn't problematic is that ageism is an irrational behavior that causes unnecessary problems wherever and whenever practiced, i.e., in everyday private life, in public life, in politics, culture, economy, etc. Therefore, it seems obvious to create not just legal regulations against ageism, but also various policies in order to influence culture in all spheres of a society, and in business this means to influence corporate climate and organizational behavior.

Anti-ageism policies in business should vary in their objects, i.e., if they are directed toward younger employees or older ones (especially if they are to be consistent with other anti-discriminating policies). They should vary in view of the core business of a company or even a whole sector of economy if certain age in terms of experience and psycho-physical requirements is necessary. Finally, they should vary concerning not just rhetoric but real inclusion of different age groups in a business primarily because this seems to be rational economic behavior. Rapid rise of aging in humans and perhaps parallel rise of ageism should be recognized, embraced, and confronted if needed, and so far these seem obvious no matter if actual policies are mostly protective and not so proactive.

Famous quote by Leonardo da Vinci goes: "While I thought that I was learning how to live, in fact I was learning how to die." This is

something that each one of us, children of the twenty-first century, has to learn for ourselves before we learn it as society of humans.

Synonyms

Principal-agent conflicts; Principal-agent theory

Definition

Agency theory is a concept which perceives the company as a nexus of contracts between various actors (Fama & Jensen, 1983a, b; Jensen & Meckling, 1976) who cooperate in order to maximize firm profit. It “recognizes conflicts of interest between different economic actors, formalizing these conflicts through the inclusion of observability problems and asymmetries of information” (Hart, 1989:1758–1759).

To achieve the organizational goals, actors need to engage in a number of relations which are described in contracts (Jensen & Meckling, 1976) specifying goals, procedures for performance assessment, and the distribution of profits. Following the rationale on the division of labor, these contracts describe the work which is delegated by principals to a number of agents. Since actors tend to maximize their utility, naturally their interests are of conflicting character (Jensen & Smith, 1985).

Agency theory has been widely adopted by numerous research in organizational studies (Dalton et al., 2007; Eisenhardt, 1989; Gomez-Mejia & Wiseman, 1997) to analyze the potential lack of alignment of goals, preferences, and actions between agents (managers) and principals (shareholders) (Nyberg et al., 2010: 1030). Recently, agency theory has also used in studies in political science, law, and sociology (Shapiro, 2005; Luh Lan and Heracleous, 2010).

Introduction

Agency theory, known also as principal-agent theory, is one of the most influential concepts which has been largely used in management, finance, and economics studies. It conceptualizes contractual relationships between different actors and analyzes the conflicts of interests which characterizes these relationships. According to the theory, actors who engage in contracts are motivated by rational preferences and driven by the goal of utility maximization. Thus, as a consequence they find themselves acting in conflict with other individuals (Simon, 1959).

The development of the theory dates back to 1976 and the seminal paper by Jensen and Meckling (1976) and works by Ross (1973) and Mitnick (1975), followed by a number of later works by Fama and Jensen (1983a, b), Jensen and Smith (1985), and Shleifer and Vishny (1997). Its prepositions are embedded in the ongoing discussion of the economics of contracts (Hart, 1995; Hart & Moore, 1988), firm theory (Coase, 1937; Demsetz, 1983), transaction costs economics (Williamson, 1975), and information asymmetry (Akerlof, 1970; Stigler, 1961). Agency theory addresses the weaknesses of the neo-classical economics and analyzes behavioral patterns within the firm. It views the firm as a production set and emphasizes the decision-making role of the professional managers. In sum, the theory is based on the assumptions of (1) the goal maximization by individuals, (2) the conflicts of interests between different actors, and (3) asymmetry of information.

Agency Conflicts in the Context of the Firm

Agency theory addresses the contractual character of the organization reality. Specifically, this theory helps to explain relations between actors at different organizational levels. Orts (2013) distinguishes two general types of agency relations: internal and external. Internal agency relations are found in the company between employees,

supervisors, managers, directors and shareholders. The external agency relations take the form of contracts between company representatives and outside entities such as suppliers, customers and contractors.

In general, principals are interested in getting the work done at the lowest cost and the highest quality possible, while agents are interested in increasing their pay and lowering their effort (Jensen & Smith, 1985). This conflicting context is additionally complicated by the information asymmetry (Fama & Jensen, 1983a, b; Jensen & Meckling, 1976) – the situation in which principals do not observe the daily operation of agents since such monitoring is too costly. Moreover, all contracts are incomplete since future situations cannot be foreseen. This means that the so-called residual rights, i.e., the rights to decide in situations not described in the contracts, belong to agents. The conflict of interests and information asymmetry lead the problems of moral hazard, the opportunistic behavior by agents, and the risk of expropriation of principal by agents.

Moral hazard refers to the situations when actors may engage in the excessively risky situations if they do not bear the cost of the actions undertaken because they are protected by contract or their actual contribution is difficult to be observed. Opportunistic behavior of agents takes place when agents engage in the actions which are likely to maximize their utility and wealth yet are at the expense of principals. This means that principals due to the information asymmetry and the inability to control agents may be expropriated by agents. The agents' tendency to act opportunistically at the cost of their principals takes the forms of (Hart & Holmström, 1987):

- Hidden information which refers to the situations when the agent does not provide information (or purposefully hides the information) on the project/company situation to the principal.
- Hidden action which refers to the situations when the agent does not disclose (or purposefully hides) the information on his or her actions undertaken in the company/project to the principal.
- Hidden intention which refers to the situations when the agent does not disclose (or purposefully hides) the information on his or her intention towards the company/project to the principal.

In the corporate governance literature agency theory refers to the analysis between and executives as well as between shareholders and debtholders. The shareholder-manager conflict takes place in the context of the separation of ownership and control and is significantly strengthened when the ownership remains dispersed (Berle & Means, 1932/1967). The shareholder-debtholder conflict emerges when the company uses bank loans to finance its operation. Recently, the research on companies operating in countries characterized with significant ownership concentration gave rise to the analysis of the principal-principal conflict which is mirrored in the tensions between dominant (majority) shareholders and minority investors.

The conflicts between these economic actors lead to the emergence of the so called agency costs. The agency problems are present at all the levels of the organization as they emerge always when agents perform tasks on behalf of their principals, meaning where there is a need of cooperation and delegation of some work to a third party. Focusing on the optimization of contracts and the increase of organizational efficiency the theory proposes the adoption of a number of governance mechanisms in order to mitigate the conflicts and lower the agency costs. These mechanisms include: shareholder participation in annual meetings, shareholder empowerment, increased transparency and disclosure, independent and efficient board, incentive function of executive pay, whistle blowing procedures, and engagement by creditors as well as the monitoring from the public and the market. Below the two cases of shareholder-manager and shareholder-debtholder conflicts are presented.

Shareholder-Manager Conflict

Numerous studies adopt agency theory to explain the relations between shareholders

(principals) and executives (agents). Since the shareholders delegate the work to professional managers they face all above listed problems related to the conflict of interest and information asymmetry. Specifically, the conflict between shareholder and a professional manager derives from the following three sources (Jensen & Smith, 1985):

- Choice of effort – illustrates the tendency of the manager to lower his/her effort to improve firm performance. The rational manager would carefully assess whether it pays off to undertake the effort and work.
- Differential risk exposure – addresses different possibilities to diversify risk by shareholders and managers. Shareholders may invest in a number of companies, what lowers their risk exposure and hence encourages them to engage in more risky projects. On the contrary, the manager invests all his/her resources (time, reputation, experience) in one company and would react differently to avoid excessive risk exposure. This observation explains the managerial tendency to pursue firm diversification and increase the size of the company – both strategies lower the risk exposure by the manager, yet they do not increase shareholder value.
- Differential horizons – refers to the potentially indefinite investment by shareholders and time-bounded engagement by the managers in a firm. This impacts the patterns of behavior of shareholder and managers, specifically, when managerial contracts cease or when managers are about to retire. Hence, executives would tend to lower the cash flow upon their departure from the company.

According to the positive view of agency theory, managers who maximize their utility acting at the expense of their principals are rational economic actors. They naturally engage in actions which may expropriate shareholders but which increase their (managers') wealth. Managers may limit the scope of financial reporting in order to prevent the access to information by shareholders about financial conditions of the firm. The most

frequently observed actions undertaken by managers to increase their utility include (Shleifer & Vishny, 1997): frauds, inefficient management, the increase of corporate expenses (business travels, executive pay, perks), short-term orientation, excessive size of the firm (usually in the form of mergers and acquisitions), excessive and economically unjustified diversification, risk aversion which lowers shareholder wealth. In addition, managers may manipulate accounting data in order to portray their performance as much better than the actual results are (e.g., early booking of revenues, increasing or decreasing cash reserves, treating costs as investments). Finally, the evidence indicates the abuse of selected components of the executive remuneration which does not correlate with or increase shareholder value. Such actions include the abuse of stock options, the short-term orientation of incentive schemes, excessive payment of bonuses in cash, or introducing the so-called "guaranteed bonus".

Jensen and Meckling (1976) argue that due to the lower investment in the company, managers treat corporate expenses in a different way. Particularly, the ownership of 1% of shares by a managers means that he or she covers 1% of the costs (for instance, for fancy office furniture), while enjoys 100% of it. For the manager, who is simultaneously the owner of the firm, the benefit is similar, yet the cost corresponds proportionally with percentage of shares owned. Thus, executives rationally are interested in increasing corporate spending, especially when their financial investment on the company is low.

To address the above-listed problems, the normative view of agency theory offers mathematical studies to structure the optimal contract. Such contract considers the actors' preferences as well as a number of attributes including (Eisenhardt, 1989; Shapiro, 2005) the length of principal-agent relationship, organizational structure and form, characteristics of industries, organizations, and employees (technology, diversification, ownership structure, the so-called programmability and definability of the task, and the organizational environments.

Majority-Minority Shareholder Conflict

The concept of agency theory initially did not elaborate on the conflicts between majority shareholder and minority investors. These problems were brought to the discourse of the analysis on ownership structure in continental Europe, Asia, and Latin America, developing and emerging economies. While the concentrated ownership understood as the possession of a large stake by a single shareholder is viewed as a potential monitoring mechanism efficient to control opportunistically behaving managers, it may lead to other problems identified as the principal-principal conflict. The principal-principal conflict, known as the second type of agency problem, demonstrates itself in a number of actions undertaken by the majority shareholder (blockholder) which increases his/ her private benefits and leads to the expropriation of minority shareholders (Bebchuk & Roe, 1999; Thomsen & Pedersen, 2000). Due to its dominant position during shareholder meeting and on the board the majority shareholder may engage in actions which increase his/her wealth and do not distribute the created value to fragmented minority shareholders.

The principal-principal conflict may take different forms having a direct impact of profit redistribution and financial performance as well as having an effect on decision making process and firm transparency. Specifically, majority shareholder may block dividend payouts and exercise the so called related party transactions which serve to shift profit from the listed company to entities fully controlled by him/her. Majority shareholders may also dominate the boardroom appointing directors and in effect take control over the decision process. They may lower the scope of reporting depriving minority shareholders of the access to the information on actual performance and strategic developments of the company.

Shareholder-Debtholder Conflict

The conflict between shareholder and debtholder refers to the situation when the firm expansion is financed in the form of debt and when the shareholder has “the opportunity to design a whole hierarchy of fixed claims on assets and earnings, with premiums paid for different levels of risk”

(Jensen & Meckling, 1976:334). The main aspect of the conflict addresses the transfer of risk to debtholder if certain projects are undertaken after the contract with the debtholder is written. This means that for the debtholder it matters if the finance is provided before a given investment in a possibly risky project as compared to the situation when the shareholder invests first in a risky project and then raises additional funds to finance it in the form of debt.

The shareholder-debtholder conflict arises with the shareholder decision which transfers the wealth from the firm to the shareholder and hence, has the effect on the risk of providing finance by the debtholder. The decision decreasing the firm value which constitutes the sources of the shareholder-debtholder conflict includes (Jensen & Meckling, 1976):

- Dividend payouts lower the value of debt if the finance was granted without the consideration of the payouts (La Porta et al., 2000).
- Claim dilution refers to the increase of the existing debt which decreases the value of the prior debt raised.
- Assets substitution refers to the investment of assets in the project of higher risk which decreases the value of the debt.
- Underinvestment addresses the situation when the future value of the firm is based on its investment opportunities. The withdrawal of the firm from NPV positive projects may impact the value of debt.

This conflict is based on the divergent interests between shareholders and debtholders – since debtholders are aware of this conflict of interest they will anticipate the possibility that shareholder would engage in highly risky projects once the funds are granted. Thus, debtholder adopt a number of mechanisms to project their position and to control the actions undertaken by shareholders.

Excessive Loyalty

Recently the emergence of an additional agency problem in the nexus of contracts within the organization has been recognized. While agency theory focuses on the opportunistic behavior of

managers and conflicts of interests between shareholders and managers, Morck (2010) argues that agents may reveal an excessive loyalty towards principals. This may have an effect on their behavior and may lead to the uncritical actions undertaken by agents following the order and expectations of principals. The agency shift of loyalty and the lack of rational assessment are the products of the agent's willingness to obtain acceptance within the organizational hierarchy.

Agency Costs

Agency Costs of Equity

Agency theory identifies conflicts between shareholders and managers and suggests the mechanisms to shape managers' behavior to mitigate these costs. According to Jensen and Meckling (1976) agency costs of equity include:

- The monitoring expenditures by the principal are spent on the control mechanisms which limit the discretion of the manager. In addition, the incentive mechanisms which motivate managers to act in the interest of shareholders.
- The bonding expenditures by the agent – the actions and mechanisms adopted by the manager to assure that undertaken actions will not harm shareholders or that shareholder will be compensated for such actions.
- The residual loss – is understood as “the dollar equivalent of the reduction in welfare experienced by the principal as a result of this” . . . “divergence between the agent's decisions and those decisions which would maximize the welfare of the principal” Jensen and Meckling (1976:308). The residual loss indicates also that the full enforcement of the contract exceeds its benefits (Fama & Jensen, 1983a). Principals (shareholders) are aware of this loss as inevitable.

While this breakdown of agency costs remain conceptual, there have been attempts to measure them. The indirect approach to calculate agency costs include to the loss of market value of a firm, value of fraud or the premium at which majority

stakes are traded (Shleifer & Vishny, 1997). Ang et al. (2000) offers an interesting analysis using two measures of (1) operating costs versus annual sale and (2) annual sale versus total assets which are compared within two sample subsets of companies where the manager is the owner versus the companies where the managers in an outsider. The first variable measures the costs understood as the excessive corporate spending and the second measure illustrates the effort undertaken by the manager. The results indicate the agency cost for manager-outsider at the level of 65,000 dollars annual (for the operating costs versus annual sale measure) and 180,000 dollars (for the annual sale versus total assets measure).

Costs of Free Cash Flow

Agency costs of free cash flow refer to a firm's own substantial cash flow at disposal with the lack of promising NPV (net present value) projects. The overinvestment in project characterized with insufficient expected profitability leads to decrease of the firm value (Jensen & Meckling, 1976). Agency costs of free cash flow are driven by the managerial tendency to increase the size of the firm (empire building) and increase of executive pay (Jensen, 1986).

Costs of Debt

The agency costs of debt are the derivative of the shareholder-debtholder conflict. Since debtholders anticipate the shareholders actions decreasing the firm value after the funds are raised, they incorporate the risk and implement measures to protect the value of debt. Hence, the agency costs of debt include:

- The incentive effects associated with highly leveraged firms which illustrate the residual loss when the firm needs to raise funds in the form of debt and is limited in its investment decisions – instead of the more risky (and potentially more promising) project it has to choose a less risky project.
- The monitoring costs which refer to the contracts limiting decision of managers who may engage in projects lowering the value of debt. The covenants on the indenture provision limit

the managerial discretion and protect debtholders.

- Bankruptcy and reorganization costs which include costs of assets relocation and residual claims rearrangement in the case of financial distress of the firm.

Residual Claims

Agency theory analyzes contracts within the organizational context which: specify decision-making process, define residual claims, provide mechanisms for control of agency conflicts, and decide about resource allocation. Jensen and Meckling (1983b) argue that different organizational and legal forms are characterized with different distribution of residual risk. Residual risk is defined as the risk between the firm revenues and payment to an agent and is bear by the group of the so-called residual claimants who control the rights to net cash flows.

The decision process is divided into two main stages (Fama & Jensen, 1983a):

- Decision management which encompasses initiation (generation of proposals) and ratification (choice of the decision).
- Decision control which includes implementation (execution of decision) and monitoring (measurement of performance and implementation of rewards).

From the perspective of the contract structure in organizations, two options of the relations between the risk-bearing and decision processes are possible (Fama & Jensen, 1983a): (1) the separation of decision management from decision control (when residual risk bearing is separated from decision management) and (2) the combination of decision management and decision control (when residual risk bearing is combined with decision management). The separation option gives rise to the emergence of a wider group of residual claimants what allows to share risk. This model is used in large firms, public listed corporations, non-profit organization, closed investment funds which require the

increased specialization of knowledge, and diffusion of monitoring functions (Fama & Jensen, 1983a). The model based on the combination of decision management and decision control reduces the number residual claimants and posts a greater risk on them. This model is found in smaller firms and family controlled companies which are limited in the appointment of individuals who play the monitoring functions. The monitors need to be selected from the group of residual claimants and not on the basis of their experience and skills (Fama & Jensen, 1983a).

Practical Implications

Agency theory has been widely adopted in management and finance studies which propose the paradigm of shareholder value maximization (Vogel, 2005; Zumbansen, 2009) focusing on the financial performance of the company (Bainbridge, 2012). Foundations of this theory gave rise to further works analyzing the most efficient structures and governance mechanisms (Jensen and Meckling, 1983b). Shareholders, who in the case of public corporations become the residual claimants, are willing to introduce and use control mechanisms to discipline managers (Eisenhardt, 1989; Hung, 1998) to mitigate the conflicts of interests, to lower the costs, and to assure for high efficiency. The governance mechanisms relate to:

- The exercise of shareholder rights (participation in annual meeting, shareholder activism, the disciplinary role of the majority shareholder, monitoring over blockholders) (Shleifer & Vishny, 1997; Mallin, 2004).
- Efficient board work including the company bylaws and regulation, specialized committees (Fisch, 2004; MacAvoy & Millstein, 2003; Carter & Lorsch, 2004).
- Structuring executive compensation which should include performance related component and should align the interests of managers with those of shareholders via managerial ownership.

Studies based on the assumption of agency theory led to the development of corporate governance understood as a concept that introduces control, monitoring, and incentive mechanisms in a company with the goal of minimizing the conflicts between shareholders and executives or shareholders. In the words of agency theory, corporate governance is perceived as a structure that assures investors to receive return on their investments (Shleifer & Vishny, 1997) or a set of constraints that forms the ex-post distribution of wealth (Zingales, 1997).

Criticism

The fundamental assumption of agency theory based on the self-interest and opportunistic behavior has been criticized. Firstly, the theory suggests that the shareholder interest and financial performance prevail over other company goals (Allen & Gale, 2000; La Porta et al., 1999). It is believed to contribute to the so-called financialization of the company (McSweeney, 2008). Secondly, agency theory emphasizes the economic rationality and focuses on the individual utility which may be limited by a number of organizational and environmental attributes. Thirdly, it offers a very simplistic view of the firm neglecting other stakeholders such as employees, communities, suppliers. And finally, agency theory provides the legitimization of illegal or unethical behavior which are defined as economically rational.

In the opposition to agency theory, the organizational studies have developed other conceptual frameworks including stewardship theory, managerial hegemony theory (Barney & Hesterly, 2008), team production theory (Blair & Stout, 1999), and stakeholder theory (Freeman, 1984; Freeman & Reed, 1983). These approaches offer different perspectives on the managerial role in the company and call for inclusion of other stakeholder in the recognition of the firm's responsibility and duties (Tricker, 2015).

Agency Theory and Sustainability

While agency theory offers an economic perspective of relations between principals and agents, it is also widely adopted in sustainability research. In the traditional approach, the shareholder utilized agency theory findings to focus on financial performance and assure for creation of shareholder value. With the growing interests towards sustainability, shareholders and stakeholders are interested in improving ESG performance which on the one hand adds to the rage of corporate performance and on the other remains crucial for increasing shareholder value. Put differently, the enumerated practical implications are now adopted with the intention to assure for ESG performance – investors are interested in enhanced sustainability disclosure to make investment decision, they develop monitoring company ESG performance. Also boards with regard to composition and structure (size, independent directors, female directors, CSR board committee) are found to contribute to better monitoring of executives with regard to ESG performance. Finally, KPIs based on ESG and sustainability measure are used to structure executive compensation to motivate managers to improving ESG performance.

Agenda 2030

► Global Governance

Agenda21 (UN)

Benedetta Siboni
Department of Management, Alma Mater
Studiorum Università di Bologna, Forlì Campus,
Italy

Definition

Agenda21 supports sustainable development in the twenty-first century, via an action plan used to address urgent social and environmental issues. It is promoted by the United Nations (UN) and has been signed by 183 heads of state around the world, first during the United Nations Conference on Environment and Development in Rio de Janeiro in 1992, and subsequently, in 2002, during the World Summit on Sustainable Development.

Agenda21 is based on the premise that human societies cannot continue along their current path. It seeks to develop new pathways that bridge the social and economic gap between and within nations, focusing on the human issues that are poverty, hunger, disease, and illiteracy, and environmental issues that see the destruction of the

world's fragile ecosystems. Agenda21 provides a list of objectives and activities to be implemented that aim to promote sustainable development. Its target is states, governments, nongovernmental organizations, and the private sector, urging them to create a global partnership to collaborate with all stakeholders in social and economic development that improves quality of life in a way that is environmentally sustainable.

Introduction

According to the most popular definition, sustainable development is a “development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (WCED 1987). Since the 1970s, the UN has committed to promoting sustainable development. A series of high-level international conferences has resulted in recommendations to national governments, as well as to multinational and national corporations, to support sustainable development (Siboni and Sangiorgi 2013).

Agenda21 is central to the UN's efforts, providing a plan for action that lists objectives and activities aimed at addressing the urgent need for social and environmental reform in order to achieve sustainable development in the twenty-first century. Agenda21 was presented alongside the Rio Declaration, the Conventions on Climate Change and Bio-Diversity and the Declaration on Forests during the UN Conference on Environment and Development (UNCED) held in Rio de Janeiro in 1992, the first global UN gathering of heads of state to debate the state of the environment. During the conference, Agenda21 was signed by 183 heads of state, securing their commitment to policies supporting the objectives of the Agenda.

In 1997, the UN General Assembly held a special session (“Rio+5”) to assess what, if any, progress had been made since Agenda21 was signed. The conference concluded that little progress had been made, with an increased disparity having emerged among states, both in terms of the economy and the environment. In response, the General Assembly adopted two further programs

aimed at reviving and strengthening commitment to sustainable development: the “Programme of Work of the Commission for 1998–2002” and the “Programme for the Further Implementation of Agenda21,” which included an action plan for the following 5 years.

The UN’s commitment to fulfilling Agenda21 was confirmed in 2002 during the UN World Summit on Sustainable Development, along with the achievement of the Millennium Development Goals. During 2012, the Fourth UN World Summit on Sustainable Development was held in Rio de Janeiro, 20 years after the first Summit (called Rio+20). In its most recent document, “The future we want” (UN 2012), the importance of Agenda21 was reaffirmed. While this is not a binding agreement, it emphasizes to nation states the importance of implementing sustainable development policies.

While the principal responsibility of implementing Agenda21 remains with national governments, a specific section of the document is devoted to local authorities (Chapter 28), to encourage them to work with stakeholders to formulate and enact a local plan for sustainable development. According to Scherr and Barnhizer (1997), Agenda21 has been most successful at a local rather than national level.

In Europe, the impetus for implementing Agenda21 has been the initiative “Campaign of Sustainable Cities,” which was initially supported by five local authority networks with the participation of the European Commission’s Environment General Directorate. The Campaign was launched during the European Conference for Sustainable Cities held in Aalborg in 1994 and continued during the Fourth European Conference for Sustainable Cities held in 2004 again in Aalborg, where cities agreed to fulfill the Aalborg Commitments, a list of sustainable objectives to be implemented at the local level. The Alliance for Sustainable Cities was confirmed during the Fifth European Conference of Sustainable cities held in Siviglia in 2007, which was followed in 2010 by the Sixth European Conference of the Alliance held in Dunkirk, during which two declaration were approved: The Dunkirk 2010 Declaration on Local

Sustainability and the Call 2010 on Climate Actions, which commits cities to a transition to a green and sustainable economy while also reinforcing the need for cities to acknowledge their role to work closely with national governments toward the goal of sustainable development.

What Is Agenda21?

Agenda21 lists a plan of objectives and actions to support sustainable development at a global, national, and local scale. The overarching themes of the Agenda are the need to urgently address critical issues confronting global society in the twenty-first century. The themes address the intertwining concerns of the climate and society that create a widening gap between and within nations relating to poverty, hunger, ill-health, and illiteracy, and the continuing deterioration of the world’s ecosystem.

The Agenda is founded on the idea that no nation can confront these emergencies alone. It calls for the establishment of a new global partnership for sustainable development, in which nation states engage in a continuous dialog, inspired by the need to achieve a more efficient and equitable world economy, particularly in light of the increasing interdependence of the community and economy of nations. While implementing the Agenda’s objectives and actions is foremost the responsibility of national governments, the document encourages international cooperation, inviting organizations at all levels, from international to national to regional and local, to contribute to this effort. The broadest public participation and the active involvement of nongovernmental organizations and other groups are also encouraged. In fact, Agenda21 promotes a “joint responsibility” of citizens, the public sector and stakeholders, hence, encouraging a synthesizing of the political, organizational, governmental, and individual. In such a context, the traditional conception of the role of government is overturned in favor of a participatory one that is flexible and accessible to a wide range of social participants, aimed at engaging stakeholders in the widest

possible sense, in order to develop a shared sustainable plan for the community.

According to Agenda21, both the economic policies of individual countries and international economic relations are crucial to achieving sustainable development. In fact, the development process needs a dynamic and stable global economy, in which developing countries are not weighed down by external debt, and in which there are no barriers restricting access to markets, as well as fair commodity prices and terms of trade.

Key principles underpinning the Agenda are democracy, subsidiarity, responsibility, transparency, public involvement, in terms of developing a decision process. In terms of environmental governance, the foundations are prevention, precaution, polluter pays, cooperation, and act within the ecosystem.

Table 1 shows the contents of the document, which start with a preamble, followed by 40 chapters in four sections.

Each chapter includes several intervention areas, which are described in terms of the basis for action, objectives, activities, and means of implementation. However, Agenda21 is a dynamic program with the potential to evolve over time as needs and circumstances change. For instance, Chapter 40 on “Information for decision-making” includes the following two areas of interventions:

“A. Bridging the data gap”:

- Basis for actions highlights the need for:
 - Capacity (particularly in developing countries) for collection and assessment of data on the issues covered by the chapters of Agenda21 in order to indicate the status and trends that relate to the global ecosystem and socioeconomic variables, to enable decision-makers to make informed decisions
- Objectives refers to the need to:
 - Achieve more cost-effective and relevant data collection and assessment by better identification of users
 - Strengthening of local, provincial, national, and international capacity to

collect and use multisectoral information in decision-making processes

- Developing or strengthening the means of ensuring that planning for sustainable development in all sectors is based on timely, reliable, and usable information
- Making relevant information accessible both in terms of form and at the time required to facilitate its use
- Activities relates to:
 - Development of indicators of sustainable development
 - Promotion of global use of indicators of sustainable development
 - Improvement of data collection and use
 - Improvement of methods of data assessment and analysis
 - Establishment of a comprehensive information framework
 - Strengthening of the capacity for traditional information
- Means of implementation implies:
 - Financing and cost evaluation, that is, average total annual cost (1993–2000) estimated at about \$1.9 billion from the international community on grant or concessional terms
 - Institutional means, that is, the activities related to development data of agencies and institutions of the UN system should be more effectively coordinated, perhaps through an equivalent and complementary “Development Watch,” which with the existing Earthwatch should be coordinated through an appropriate office within the UN to ensure the full integration of environment and development concerns
 - Scientific and technological means, that is, the need to develop guidelines and mechanisms for rapid and continuous transfer technologies on data-collection and information technologies as well as appropriate training for human resources for such activities
 - Capacity-building, that is, all countries should strengthen their capacity to collect, store, organize, assess, and use data in decision-making more effectively

Agenda21 (UN), Table 1 Table of contents of Agenda21

1. Preamble
Section I. Social and Economic Dimensions
2. International cooperation to accelerate sustainable development in developing countries and related domestic policies
3. Combating poverty
4. Changing consumption patterns
5. Demographic dynamics and sustainability
6. Protecting and promoting human health conditions
7. Promoting sustainable human settlement development
8. Integrating environment and development in decision-making
Section II. Conservation and Management of Resources for Development
9. Protection of the atmosphere
10. Integrated approach to the planning and management of land resources
11. Combating deforestation
12. Managing fragile ecosystems: combating desertification and drought
13. Managing fragile ecosystems: sustainable mountain development
14. Promoting sustainable agriculture and rural development
15. Conservation of biological diversity
16. Environmentally sound management of biotechnology
17. Protection of the oceans, all kinds of seas, including enclosed and semi-enclosed seas, and coastal areas and the protection, rational use and development of their living resources
18. Protection of the quality and supply of freshwater resources: application of integrated approaches to the development, management and use of water resources
19. Environmentally sound management of toxic chemicals, including prevention of illegal international traffic in toxic and dangerous products
20. Environmentally sound management of hazardous wastes, in hazardous wastes
21. Environmentally sound management of solid wastes and sewage-related issues
22. Safe and environmentally sound management of radioactive wastes
Section III. Strengthening the Role of Major Groups
23. Preamble
24. Global action for women towards sustainable and equitable development
25. Children and youth in sustainable development
26. Recognizing and strengthening the role of indigenous people and their communities
27. Strengthening the role of nongovernmental organizations: partners for sustainable development
28. Local authorities' initiatives in support of Agenda21
29. Strengthening the role of workers and their trade unions
30. Strengthening the role of business and industry
31. Scientific and technological community
32. Strengthening the role of farmers
Section IV. Means of Implementation
33. Financial resources and mechanisms
34. Transfer of environmentally sound technology, cooperation and capacity-building
35. Science for sustainable development
36. Promoting education, public awareness and training
37. National mechanisms and international cooperation for capacity building in developing countries
38. International institutional arrangements
39. International legal instruments and mechanisms
40. Information for decision-making

Source: UN (1992)

“B. Improving availability of information”

- Basis for actions highlights that:
 - Even where information is available it is not adequately managed, because of shortages of financial resources and trained manpower, lack of awareness of the value and availability of such information and other immediate or pressing problems, especially in developing countries
- Objectives refers to:
 - Strengthened technical assistance for existing national and international mechanisms of information processing and exchange
 - Strengthened national capacities
 - Ensuring full participation of, in particular, developing countries in any international scheme under the auspices and organizations of the UN system for the collection, analysis, and use of data and information
- Activities relates to:
 - Production of information usable for decision-making
 - Establishment of standards and methods for handling information
 - Development of documentation about information
 - Establishment and strengthening of electronic networking capabilities
 - Making use of commercial information sources
- Means of implementation implies:
 - Financing and cost evaluation, that is, an average total annual cost (1993–2000) estimated at about \$165 million from the international community on grant or concessional terms
 - Institutional means, that is, strengthening of existing institutions, as well as of cooperation with nongovernmental organizations
 - Capacity-building, that is, developed countries and relevant international organizations should cooperate, in particular with developing countries, to expand capacity to receive, store, and retrieve, contribute, disseminate, use,

and provide appropriate public access to relevant environmental and developmental information, by providing technology and training to establish local information services

- Scientific and technological means, that is, developed countries and relevant international organizations should support research and development in hardware, software, and other aspects of information technology, in particular in developing countries

Air Contamination

► Air Pollution

Air Pollutants

► Air Pollution

Air Pollution

Stefania Massari, Marcello Ruberti, Pier Paolo Miglietta and Federica De Leo
University of Salento, Lecce, Italy

Synonyms

[Air contamination](#); [Air pollutants](#); [Air quality](#); [Atmospheric pollution](#); [Smog](#)

Definition

Air, as known, being a heterogeneous mixture of various gases and particles of different types and sizes, has a variable composition in space and time. For this reason, it is really difficult to define a conventional standard of air quality characteristics and its related pollution conditions.

Starting from this preamble, it could be anyway possible to define, in an indirect way, the concept of air pollution based on the description of the substances (solid, liquid, or gaseous) and phenomena (physical, chemical, and biological) that characterize this state.

In this regard, it is usually distinguished between “contaminant” and “pollutant.” Contaminants are those substances that, added into an environmental system (i.e., in the atmosphere), cause a chemical and/or physical deviation from the average geochemical composition. A pollutant is instead a contaminant that can cause, directly or

indirectly, harmful effects to environment and life (Williamson 1973).

In essence, however, this distinction is less clear than it appears, especially with regard to the earth’s atmosphere: any contaminant, in fact, in the long term, could tend to become a pollutant as a result of the complex chemical reactions to which it could potentially be subject. Therefore, in many situations, contaminants and pollutants are considered synonymous (Zannetti 1990).

According to the above, it would be considered polluted, therefore, the air altered: in its chemical-physical parameters (i.e., noise, heat); in the quantitative relationships of the substances present in it; and/or by the presence of substances outside its average standard composition (or established by law).

Introduction

Air pollution has arisen when mankind began to exploit the non-renewable resources of our planet, in particular the fossil energy sources. Its negative effects can be amplified – in local area and for limited time periods – by different meteorological and climatic factors, such as thermal inversions. As known, this is a well-known natural atmospheric phenomenon for which there is a rise in the thermal gradient with altitude. Under these conditions, the suspension of convective air motions and stagnation near the soil of the pollutants occur. This is exactly the situation that happened in December 1952 in London known as “The Great Smog of London,” when thousands of people prematurely died in a few days (Rodriguez 2014).

Air pollution can be investigated as “external” or “outdoor” pollution (of the atmosphere and, in particular, of the troposphere) and “internal” or “indoor” pollution, typical of closed small environments (i.e., houses and workplaces). The types of pollutants, for the two situations, are usually very different. For indoor pollution, in particular, the characterization of the corresponding pollutants is much more difficult than that of outdoor pollution because its air composition is very variable and characterized by substances not

detectable outdoor (i.e., Rn, H₂CO). Furthermore, the complete understanding of the problems of indoor pollution is still affected by the scarcity of common data from standardized and large-scale monitoring studies (Hernandez and Peden 2014). For these reasons, in this chapter, we will refer mainly to outdoor (atmospheric) pollution and, particularly often, to the contamination of that troposphere zone called PBL (planet boundary layer).

Sources and Pollutants

Pollutants are usually divided into “primary” and “secondary.” The substances directly emitted from sources into the atmosphere and which, often, persist in their native molecular or atomic state (i.e., carbonic, nitrogen, sulfur, and halogen compounds and particulate matter) – are called primary, whereas those substances that, in particular atmospheric conditions, originate from the transformation or chemical reaction between the primary pollutants or between the primary precursors and some natural components of the atmosphere are considered secondary (i.e., tropospheric ozone, aerosols, acids, and nitrogen dioxide) (Daly and Zannetti 2007). This distinction is important for the purposes of the related control measures: in fact, often the reduction in the atmosphere of a primary precursor does not necessarily lead to a proportional reduction of the corresponding secondary pollutant. This is principally due to the complex chemistry between the different particles of the atmosphere.

Atmospheric pollutants can have different origins (emission sources): natural and man-made. The natural sources are very different: gaseous emissions from biological processes; ash and oxides from volcanoes or fires; radioactive emissions; dust and spores from wind-blown soil; aerosols from oceans; geological debris containing asbestos from screes; etc. Also the anthropogenic sources can be numerous; in fact, the emissions can come from: vehicular traffic, industrial activities, home heating, agricultural and zootechnical sector (intensive farms), waste

treatment plants (incinerators, landfills, and composting plants), etc. (Gordon et al. 2014). In this regard, if the source of the emissions is conveyed into a chimney or located in a fixed and limited place, it is a point source of pollution; vice versa, if this does not happen, then it is a non-point source (NPS) of pollution or area source.

The most widespread groups of atmospheric pollutants, according to the WHO's (World Health Organization) “Air quality guidelines” (2006), and among the most monitored in the world are sulfur compounds (SO₂, COS, H₂S, CS₂, etc.), mainly produced by the combustion of fossil energy sources, volcanic eruptions, and decomposition of organic matter; oxides of nitrogen or NO_x (NO as primary pollutant and NO₂ as secondary pollutant from the reaction of NO with O₃) from the high temperatures of combustion processes; carbon compounds (CO and CO₂) from natural sources, motor vehicles, and thermal plants; ozone (O₃), secondary highly oxidizing and toxic pollutant, from the reaction involving solar radiation and nitrogen dioxide; free radicals (OH[•], HO[•], and NO[•]), very reactive secondary pollutants, originating from complex reactions involving O₃ and NO; volatile organic compounds (VOC), which include both hydrocarbons and other compounds containing oxygen and/or halogens, from various chemical products (solvents, paints, fuels, etc.); polycyclic aromatic hydrocarbons (IPA) from combustions in general; halogenated compounds (HCl, HBr, HF, CFC); heavy metals (Cd, Cr, Pb, Hg), mainly from the chemical industries; and particulate matter (PM₁₀, PM_{2.5}, and PM_{0.1}), complex pollutants (primary and secondary) which are produced mainly by combustion processes or chemical-physical reactions directly in the atmosphere.

Effects

The effects, on ecosystems and health, of the pollutant emissions depend not only on the specific fuel or plant (its age and its state of maintenance) but even on factors linked to atmospheric phenomena (i.e., rains, convective and dispersive motions of air currents, and so on) and to the

orography of places, which greatly affect the persistence of pollutants near the ground.

Globally, the most significant adverse effects of air pollution on ecosystems can be acid deposition (see ► [“Acid Rain”](#)), ► [“Greenhouse Effect”](#), and ozone hole. Other effects, on limited areas, are photochemical smog and eutrophication (Saxena and Naika 2019). As known, acid rain originates from the reaction of CO₂, NO_x, and SO₂ with the water vapor of the atmosphere and can cause serious damage to living beings and to anthropogenic and natural environment. The greenhouse effect is a climatic phenomenon that allows the warming (see ► [“Global Warming”](#)) of the earth’s atmosphere by the shielding of some greenhouse gases (CO₂ and CH₄, mainly). The ozone hole, due to the preponderance of organic halogenated compounds, causes the reduction of the natural protection of ecosystems against ultraviolet (UV) radiation from the sun.

The risks of air pollution to health are not yet fully clarified. However, the possible effects may be acute (in the short term) and chronic (in the long term). Short-term ones are investigated by medical researches on a daily basis. Those of long term, which are more difficult to identify and characterize, are subject by long-term cohort investigations. The acute risks extend from simple irritations of the respiratory system up to the possible onset of severe respiratory and cardiovascular diseases caused by ozone, nitrogen, and sulfur oxides. Prolonged exposure to some pollutants (fine particulate matter, benzene, and heavy metals) can cause asthma, chronic bronchitis and emphysema (chronic obstructive pulmonary disease or COPD), lung cancer, leukemia, and death (Kampa and Castanas 2008). The toxicity of the effects is very variable and depends obviously on the age of the subjects involved (children and old people are obviously the most sensitive), the health conditions, and the intensity of exposure.

Countermeasures

In the last 40 years, the international community has begun to take care of this problem by laws and instruments that allowed lowering the

concentrations of pollutants such as sulfur dioxide, lead, and carbon dioxide. The first international convention that aimed to protect the environment and health from atmospheric pollution was that of Geneva in 1979 (Convention on long-range transboundary air pollution or CLRTAP). Over the years, other conventions, implementation protocols, and directives have followed it. These international improvement tools have had clear positive feedback on air quality and health, but have not yet solved the problem at all.

In the industrial sector, for a long time, the polluting emissions have been strongly regulated. Industrial plants, in fact, are regularly subjected to inspections and checks by the competent control authorities and are obliged to adopt systems to reduce their impact on the environment.

To moderate air pollution, much more can and should be done by nations and people (see ► [“Pollution”](#) and ► [“Pollution Prevention”](#)): periodically checking the combustion plants and the pollutant abatement systems; reducing urban circulation in city centers and during traffic congestion; modernizing motor vehicles; choosing collective transport solutions (buses or trains); driving at moderate speed; recycling waste; moderating the temperature of heating/cooling systems; preferring energy renewable sources; adopting energy-saving tools and environmental friendly styles of consumption; and so on.

Summary

Air pollutants can alter the earth’s climate and cause danger to the quality of the environment (natural or anthropic), to ecosystems, to life, and to humans, in particular. They can also seriously affect the rightful uses of the environment by mankind. Air pollution is one of the environmental problems that most concern the populations of large urban conglomerations mainly due to the high density of emissions (that is, the quantity of pollutants emitted per unit of territory) in these places. A complete evaluation of the potential polluting effect of the thousands of substances released into the air would be quite complicated,

so only specific pollutants – characterized by a high level of environmental pollution potential – are investigated by the international scientific community. Atmospheric pollutants have direct repercussions – even at considerable distances from the place of emission – on ecosystems, especially on the most vulnerable ones, and on health. To reduce air pollution, much more can and should be done by nations and people.

Definition

Algae can be referred to as a broad, diversified class of eukaryotic, photosynthetic organisms.

They can be single-celled, multicellular, or even exist in colonies. Algae are a polyphyletic group of creatures that include Bacteria, Plantae, Chromista, and Protozoa, all classified as members of separate biological kingdoms.

Algae contain chlorophyll which gives them the photosynthetic ability to convert sunlight and carbon dioxide to produce oxygen and energy in the form of sugar. Algae are abundantly present in practically every area of oceans and other water bodies that receive sunlight.

The term “biomass” refers to any fuel made from plants that can be used to generate heat or electricity. To further meet the need for transportation fuel, biomass is turned into liquid fuels referred to as Biofuels.

The use of biofuel made from biomass resources has been promoted to meet the world’s energy needs and lower pollution emissions from the transportation industry. Using biomass and other biodegradable wastes effectively through biofuel production is a sustainable strategy.

There are 44,000 species, although the precise number varies depending on who defines “algae,” with some estimates putting the figure as high as a million (Guiry, 2012).

Examples of classes of algae are algae (Chlorophyceae), brown algae (Phaeophyceae), red algae (Rhodophyceae), cyanobacteria (Cyanophyceae), diatoms (Bacillariophyceae), yellow-green algae (Xanthophyceae), golden algae (Chrysophyceae), dinoflagellates (Dinophyceae), (Prasinophyceae and Eustigmatophyceae).

Introduction

Microalgae are a diverse group of microorganisms that have adapted to various environmental conditions in response to photooxidative stress or other adverse environmental circumstances. Many microalgae produce large quantities of triacylglycerols (TAG) as a storage lipid (e.g., 20–50% dry cell weight) (Hu et al., 2008). They are regarded as primary producers because, when exposed to sunlight, they are the predominant converters of water and carbon dioxide to biomass and oxygen (Kukwa & Chetty, 2021).

Microalgae species can rapidly develop and produce significant amounts of oil, making them

great candidates for producing biofuel oils and other lipids (Sheehan et al., 1998). Furthermore, while macroalgae generate little lipids, they are a substantial source of carbohydrates that may be converted to bioethanol or biomethane by biological conversion processes such as anaerobic digestion and fermentation (Driver et al., 2014). Furthermore, algae are considered potential feedstocks for future bioenergy production; numerous recent literature studies have focused on algal-based biofuels and bioproducts, as well as the possibilities and problems that come with them (Williams & Laurens, 2010).

This Encyclopedia chapter aims to supply a long-term perspective of algal biofuel development. Microalgae have been the focus of most of the bioenergy research and development, from basic research through conversion and implementation. As a result, microalgae will get much of the focus in this study.

Potential of Algae Bioenergy

Global demand for fossil-fuel-based energy is rising as the world’s population continues to expand. As a result of worldwide usage, fossil fuels have been depleted and will be depleted and consumed. This situation is because they are non-renewable and cannot be reused. There’s a reason biofuel is gaining popularity worldwide, especially in countries with limited financial resources and assets. (Khan et al., 2018).

Burning fossil fuels is terrible because it promotes global climate change by increasing greenhouse gas (GHG) emissions. Microalgae could be a viable renewable energy source, and they could help fulfil the Sustainable Development Goals by reducing greenhouse gas emissions. (SDGs) (Merlo et al., 2021).

It is possible to drastically reduce CO₂ emissions worldwide by using algae-based microalgae fuels, which are both environmentally friendly and non-toxic. According to one study, one kilogram of algal biomass can absorb 1.83 kg of CO₂ from the atmosphere (Paul et al., 2014). Microalgae have been hailed as a potential next-generation biofuel source because they are 10–20 times more

abundant than any other biofuel crop and do not need a lot of area or valuable biodiverse landscapes to grow (Narala et al., 2016).

Microalgae could be utilized to make a variety of biofuels. Biodiesel and biohydrogen are produced from microalgal oil (Gavrilescu & Chisti, 2005; Kapdan & Kargi, 2006; Spolaore et al., 2006).

Biofuels have been produced using microalgae. Several countries have started research programs to discover how to grow microalgae for biofuels since then (Oswald and Golueke, 1950). Microalgae production for biofuels has started in the United States, Australia, and Japan, among other countries (Salian & Strezov, 2017).

In the past two decades, algae-based biofuels have attracted much attention. Microalgae biofuels have been thoroughly explored from a technical, economic, and environmental

standpoint. The most significant focus has been paid to profitability measurements (Venkatesan et al., 2017). Microalgae's contribution to the United Nations' Sustainable Development Goals (SDGs), as well as global and climatic change, is another indicator that they will be there for a long time. More study is needed to properly understand how microalgae may help make the world a better place (Itoiz et al., 2012) (Fig. 1).

The numerous options for algae biofuel production are illustrated. There are many options for algae type and strain, including eukaryotic algae and prokaryotic cyanobacteria, the water source for cultivation, cultivation method and algae cultivation method, algae harvesting method and biofuel conversion process. These processes determine how metabolite like a triacylglycerol is extracted from algae and what type of biofuel is generated (Driver et al., 2014).

Algae Bioenergy,

Fig. 1 The building blocks of algal biofuel manufacturing

Even though both microalgae and macroalgae are viable bioenergy feedstocks, most liquid biofuels research has focused on microalgae due to their high biomass output, great oil content, and low land requirements. Macroalgae, or seaweeds, on the other hand, have the potential to make a significant contribution to algae-based bioenergy production and are of particular interest to countries with macroalgae-friendly beaches. Although ethanol synthesis from macroalgae has been shown, primary bioenergy applications for macroalgae are more for biogas production than liquid biofuels (Chen et al., 2015).

According to several studies, microalgae biofuel production has several advantages, including:

- (i) No conflict with human or animal food chains.
- (ii) High carbohydrate, protein, and oil content.
- (iii) Ability to grow in aqueous media such as wastewater, freshwater, and saline water.
- (iv) Ability to assimilate nutrients from brackish, salt, or highly polluted water.
- (v) Create a long-term O₂ generating method and employ it in photosynthetic respiration to reduce CO₂ emissions (Laurens et al., 2017).

Algae Biomass Production Systems for Bioenergy

Open and enclosed culture systems are the two kinds of culture systems used to produce biomass from microalgae (Itoiz et al., 2012). Raceways and open ponds have low initial construction and maintenance costs, low volumetric production, and difficult-to-control properties such as temperature, evaporation, and pollution. Horizontal photobioreactors, bubble columns, and flat panels yield 13-fold more volumetric biomass than raceways or ponds. They can grow only one microalgal cell (monoculture) and are less prone to contamination than open systems. Compared to open systems, enclosed systems have a higher initial construction cost. Photobioreactors offer a controlled environment tuned to the unique needs of very prolific microalgae, resulting in consistently high oil production year after year (Chisti, 2007).

The algal biofuel production method follows several steps that take you from algae growth through collection and harvest and eventually to fuel conversion (Fig. 2).

As illustrated above, there are numerous possibilities for producing biofuel from algal

Algae Bioenergy, Fig. 2 Energy production from algae via different pathways (Zewdie & Ali, 2020)

biomass. Various elements, including material and energy efficiency, infrastructure availability, CO₂ emissions, and other environmental issues, influence the criteria for selecting the optimal biomass process (Zewdie & Ali, 2021). According to Davis et al. (2011), the routes help demonstrate the resource requirements and repercussions of scaling up alternative technologies to produce algal biofuels.

Critical Issues to Algae Bioenergy Production

In 2017, the International Energy Agency's (IEA) Bioenergy Technology Collaboration Program (TCP) commissioned and released research on the status of algae-based bioenergy technology, covering many problems. This chapter is the product of literature on processing, biorefinery applications, macroalgae, and general techno-economics or sustainability problems (IEA, 2017). The following are some of the report's primary messages:

- Algae have excellent photosynthetic efficiencies and yields (up to double that of terrestrial plants, 55 tons ha⁻¹ yr⁻¹), making them an appealing target for improving the long-term sustainability of bioenergy production.
- The cost of producing and collecting algal biomass feedstocks, which is now a factor of 10–20 too high for commodity fuel generation, remains the single most significant obstacle to the commercial deployment of algae.
- The low cost of natural gas, along with the lack of consistent carbon pricing regimes, makes developing cost-competitive algae-based bioenergy products such as gaseous and liquid fuels difficult.
- Algae might be employed in an integrated biorefinery to produce higher-value food, feed, nutraceutical, and oleochemical bio-products in the near future, which could aid the development of cost-effective bioenergy production.
- Land use competition will come from other market possibilities for algal biomass, such as food and feed usage.
- Water, land, and sunlight availability, as well as nutrient demands (N, P), remain critical economic and environmental challenges, with wastewater integration providing near-term answers.
- Recent technological advancements have allowed all components of algal biomass to be used; algal biomass production is no longer just focused on achieving high lipid output.
- According to the literature, algae-based bioenergy production of primary products such as liquid or gaseous fuels is unlikely to be economically viable in the near future. Under mild maritime circumstances, macroalgae have a lot of promise as a biogas, chemicals, and biofuels crop. Its commercialization is also hampered by cost and scalability issues.
- From cultivation through product separation to Techno-economic analysis (TEA) and Life cycle assessment (LCA) and modelling, more open data sharing and standardization of analytical methodologies are critical for identifying and overcoming hurdles to low-cost bioenergy production.

Experts do not argue that microalgae are the answer to humanity's underlying energy issues, according to Merlo et al. (2021). However, they could be a part of the global answer, particularly in rural or underdeveloped areas. Microalgae biofuel could help manage the majority of global GHG emissions and climate change by partially replacing fossil fuels, which are nearing their limits. Biofuels made from microalgae are produced, processed, and used in various ways to achieve the Sustainable Development Goals.

Despite the relevance and significance of biofuel as an energy source, various technological obstacles and constraints must be overcome, according to the critical conclusions of the IEA research, to produce enough biofuel to fulfil global energy demand. Primary obstacles in bioenergy production include identifying potential species with triacylglycerides in optimal

cultivation, adaptability and development of cultures (inocula), large-scale systems, and overall cost reduction (Hu et al., 2008).

Aside from the prohibitive cost and other challenges, microalgae biofuels have a lower energy and water impact than terrestrial biofuels (Maeda et al., 2018). Microalgae may also contribute to the attainment of crucial SDGs vital to our society by creating sustainable energy. They give a lot of room for expansion and allow governments to diversify their energy mix while improving energy stability and security. As a result, petroleum supplies are limited, and rising oil prices are unavoidable as the oil peak approaches (Turiel, 2010).

Summary

Microalgae could be used to manufacture biofuels by acting as a cell factory. They are renewable, sustainable, and cost-effective biofuels that could be an alternative to liquid fossil fuels in terms of sustainability and environmental challenges. The cost of producing algae-based biofuels continues to divide experts, and it's uncertain whether they'll be able to compete effectively in the market against fossil fuels or conventional biofuels.

More sophisticated research is required to make large-scale biofuel manufacturing cost-effective. Most current R&D efforts are focused on lowering these expenses. Several businesses engaged in the commercial development of algae-based biofuels have shifted their attention to higher-value foods, feed, and speciality commodities.

One way to reduce the cost of algae-based biofuel production is to use multi-product biorefinery technology, which allows algal biomass to be sustainably processed into various bio-based commodities and bioenergy products. Applications for algae-based bioenergy are continuously being developed. Algae-based biofuel production costs must improve to compete with fossil fuels or conventional biofuels, although the requisite degree of increase is attainable.

The issues of commercialization and successful algae production for low-value energy and fuel sectors are expected to be solved in the not-too-distant future, ensuring a sustainable energy source.

Altruism

Borna Jalsenjak
Luxembourg School of Business,
Luxembourg, Luxembourg
Zagreb School of Economics and Management,
Zagreb, Croatia

Definition

Altruistic acts are acts committed with the intention to purposively help others, even at the expense of one's welfare. The English word altruism comes from Latin word *alter* which means "other". Auguste Comte is credited as the originator of the word.

Conditions for the Development of Altruistic Behavior

Various explanations on the origin of altruism and cooperation between beings exist. However, all of those have in common that they emphasize that for the existence of altruism, beings need to have at least some access to the faculty of memory, and they need to be able to distinguish and categorize different members of their and other species in some way. Ability to distinguish between members of different species in turn suggests that they also have some, at least rudimentary, understanding of different beings and their qualities (Broom 2003, p. 89; Dugatkin and Alfieri 2002). In the

context of life in general, e.g., biological altruism, the condition of intention is emitted, and the acts are only looked through the lens of consequences the act has on fitness. If the intentions were presupposed as the necessary condition, then altruistic behavior would be reserved only to humans.

Altruistic Behavior with an Intention to Act

Unlike actions in the general animal kingdom, when it comes to people, for something to be considered as an altruistic act, there is very often a presupposed intention to carry out the act with the purpose of helping others. This might be called “real” altruism. Nonetheless, even when the discussion is about human altruistic behavior, there are possible distinctions. For example, it is not the same if a person does something out of entirely selfless reasons and a wish to help others or if a person does something to help others but has some self-interest in the results of that action. Both cases can be looked at as altruistic. The difference in motives, having entirely no self-interest and having some interest, can be made more apparent by denoting altruistic acts and the use of the word altruism, as cases of “strong” and “weak” altruism (Kraut 2018).

In the case of “strong” altruism, there is no self-interest on the side of the agent, and there is a possibility of some loss. For example, one might be willing to help a stranger in the city to get around and in doing that lose its time and perhaps even be late for work. On the other hand, in the case of “weak” altruism, there is some motive for acting which is at least somewhat related to the well-being of an agent. For example, a person might again wish to help a stranger in the city, but the person wishes to leave a good impression believing that would help increase his chances of future well-being in whatever context.

Both strong and weak cases of altruism should be distinguished from self-sacrificing behavior where there is always a loss present for the agent. An everyday example of something not being self-sacrificing behavior might be the situation when someone has lunch vouchers but cannot use them

all and gives them to someone else, so they do not go to waste. Here there is no actual loss for the person giving the vouchers. A completely different situation is when someone gives their vouchers to someone and goes hungry as a result.

Definition

Altruistic CSR

The term altruism means renunciation of the self and an exclusive concern and care for the welfare

of others. Therefore altruistic CSR is a form of corporate social responsibility (CSR) that goes beyond ethical behavior to voluntarily donate time and/or money towards certain groups of stakeholders, even if the time or money commitment sacrifices part of the business profitability.

Introduction

CSR as a Concept

CSR is the internal obligation of each business entity to account for the way its activities impact the economic, social, and environmental dimensions of its environs and to ensure that this impact generates equitable and sustainable benefits and there is no harm to all the stakeholders involved.

The CSR concept developed from two sources at different times but converged as a business norm after the millennium. One source was CSR as business ethics, and the other was CSR as part of sustainable development programs promoted by the United Nations (United Nations 1992). The idea that a company should be responsive towards the society rather than simply achieve economic goals was raised through discussions on business ethics since the 1950s (Carroll 1999). CSR as part of sustainable development programs started in the early 1990s, shortly prior to the Earth Summit held by the United Nations. The conference called for cooperation to reduce environmental damages and to pursue business goals while considering environmental impacts (United Nations 1992).

Evolution Phase of Corporate Social Responsibility

If we study the evolution phase of corporate social responsibility globally, we would come across certain distinct time periods, and each of such time periods had added to or enriched the concept of CSR through the valuable researches carried on by various eminent researchers.

The first *time period of 1920–1950s* concentrated on the social responsibilities of businessmen which was quite evident from some of the works worth noting like Chester Barnard's *The Functions of the Executive* (1938), J. M. Clark's

Social Control of Business (1939), and Theodore Kreps's *Measurement of the Social Performance of Business* (1940), to point out just a few. In the second time period of the 1950s, corporate social responsibility as a concept started taking shape. Most scholars point to Howard Bowen's *Social Responsibilities of the Businessman* (1953) as the first attempt to theorize the relationship between companies and society (Carroll 1999; Preston and Post 1975; Wartick and Cochran 1985). According to Bowen, CSR "refers to the obligations of businessmen to pursue those policies, to make those decisions, or to follow those lines of action which are desirable in terms of the objectives and values of our society" (Bowen 1953). The *decade of the 1960s* "marked a significant growth in attempts to formalize or more accurately, state what corporate social responsibility means" (Carroll 1999). He suggested that some of the most prominent writers during that time were Keith Davis, Joseph W. McGuire, William C. Frederick, and Clarence C. Walton. The notion of business ethics to corporate social responsibility was introduced during this era. The *time period of the 1970s* was an era of enlightened self-interest. A breakthrough in conceptual development was observed during this period when a new study on corporate social responsibility was commissioned by the Committee for Economic Development. The Committee described corporate social responsibility as being "related to products, jobs and economic growth; related to societal expectations; and related to activities aimed at improving the social environment of the firm" (US Committee for Economic Development in Wheeler et al. 2003). There was enthusiasm and research in the field of corporate social responsibility in the 1970s (Ackerman 1973; Fitch 1976; Murray 1976). The *era of the 1980s* paved way for the development of complementary themes to CSR. A prominent development in terms of corporate social responsibility was the global debate on sustainable development that emerged in this decade (Tilbury and Wortman 2004; World Commission on Environment and Development 1987). The *era of the 1990s* was that of imbibing the concept of CSR in the field of strategic management. CSP, stakeholder theory, business ethics

theory, and corporate citizenship were the major themes that took center stage in the 1990s (Carroll 1999). Corporate social responsibility advanced with more practical applications in mind by strategic management scholars such as Philip Kotler, Nancy Lee, Michael Porter, Rosabeth Moss Kanter, and Stuart Hart. In the *twenty-first-century* expansions, the theoretical contributions to the concept and meaning of CSR had given way to empirical research on the topic and a splintering of interests away from CSR into related topics such as stakeholder theory, business ethics, sustainability, and corporate citizenship. The most optimistic perspective during this era was depicted well by D. Lydenberg (2005) in his book *Corporations and the Public Interest: Guiding the Invisible Hand*. Lydenberg saw CSR as “a major secular development, driven by a long-term reevaluation of the role of corporations in society.”

Three Forms of CSR

Ethical CSR

Ethical CSR is morally mandatory and goes beyond fulfilling a firm's economic and legal obligations, to its ethical responsibilities to avoid harms or social injuries, even if the business might not appear to benefit from this. Hence, a corporation is morally responsible to any individuals or groups where it might inflict actual or potential injury (physical, mental, economic, spiritual, and emotional) from a particular course of action (Lantos 2001). Although economic and legal responsibilities embody ethical norms about fairness and justice, ethical responsibilities embrace those activities and practices that are expected or prohibited by societal members even though they are not codified into law. Ethical responsibilities embody those standards, norms, or expectations that reflect a concern for what consumers, employees, shareholders, and the community regard as fair, just, or in keeping with the respect or protection of stakeholders' moral rights. In one sense, ethics or values precede the establishment of law because they become the driving force behind the very creation of laws or regulations.

Altruistic CSR

Fulfillment of an organization's philanthropic responsibilities, going beyond preventing possible harms (ethical CSR) to helping alleviate public welfare deficiencies, regardless of whether or not this will benefit the business itself is what altruistic CSR is all about. Altruistic CSR is equivalent to Carroll's (2000) philanthropic responsibilities and involves contributing to the good of various societal stakeholders, even if this sacrifices part of the business' profitability. The justification lies in the fact that the corporation has been entrusted with massive economic and human resources and has the power to affect many parties beyond the shareholders. Thus, there is a social contract between business and society. Philanthropic responsibilities encompass those corporate actions that are in response to society's expectation that businesses be good corporate citizens. This includes actively engaging in acts or programs to promote human welfare or goodwill. The distinguishing feature between philanthropy and ethical responsibilities is that the former is more discretionary or voluntary on the part of businesses even though there is always the societal expectation that business provides it whereas ethical responsibilities are morally mandatory.

Strategic CSR

Strategic CSR involves being responsive to societal needs that in turn would accomplish strategic business goals. Strategic CSR is central to the firm's value creating activities. By taking a strategic approach, companies can choose activities that will strengthen their competitive advantage. If CSR becomes a part of a company's overall plan, then organizations can ensure that nothing affects the need to behave ethically with their stakeholders. Strategic CSR helps companies to balance economic value with that of societal value, manage their stakeholder relationships, identify and respond to threats and opportunities facing their stakeholders, and develop sustainable business practices. *It is here that the opportunities for shared value truly lie. The success of the company and the success of the community*

become mutually reinforcing. If a social issue is closely connected to the company's business, then the opportunity to leverage the firm's resources and capabilities and benefit society is greater.

Key Issues

Altruistic CSR according to many authors (Lantos 2001) is not a legitimate corporate activity. Corporations do not have the obligation to engage in altruistic activities, but it is their responsibility to ensure that society is not harmed by their actions. One of the main challenges for business is to establish an effective CSR framework that combines both the aspects of profitability and responsibility towards the stakeholders and environment. Corporations are not altruistic, and they cannot be altruistic in a competitive environment. Hence, declaring philanthropy as CSR gives an imperfect picture of the business as well as its relationship with the society. The philanthropic approach to CSR which wants a corporation to take responsibility beyond their core business activities is problematic. Thus we need to emphasize more on strategic CSR which benefits both companies and the society.

Anglo-American Board Model (One-Tier) Versus European Model (Two-Tier)

Luisa Bosetti
Department of Economics and Management,
University of Brescia, Brescia, Italy

Synonyms

One-tier board model versus two-tier board model; Outsider system versus insider system; Shareholder-oriented systems versus relationship-based system; Unitary model versus dual model

Definition

One-tier and two-tier models are the typical expressions used to describe how corporate

governance is structured in a company, in compliance with its country's legislation.

In a one-tier model, corporate governance prerogatives are assigned to a single board, named the board of directors. This board is usually appointed by the shareholders' meeting, and according to the law, it exercises both direction and control. The one-tier model is typical of the Anglo-American countries, but it can be found in other world regions too.

A two-tier model consists of two separate corporate governance boards, which are appointed in sequence. The process starts with the appointment of the supervisory board by the shareholders' meeting; the employees can also take part in the nomination process, if it is laid down by law. Then, the supervisory board appoints the management board, which is composed of executives who are selected from outside the supervisory board. The two-tier model mainly characterizes Germany and the Rhine context.

The legislation of some European countries, such as Italy, Portugal, and the Netherlands, also envisages a third type of corporate governance model, in which two separate bodies appointed by the shareholders' meeting perform different functions: A board of directors is responsible for defining strategies and managing activities, while a board of statutory auditors monitors the company's administration and information system.

The effective functioning of corporate governance boards is key to ensuring decision-making and assessment processes based on social responsibility and sustainability principles, in the broad interest of all stakeholders.

Introduction

Policymakers, regulators, business associations, and scholars have suggested many definitions of corporate governance, all of which imply references to the various models that can be implemented.

A well-known definition of corporate governance states that it "involves a set of relationships between a company's management, its

board, its shareholders and other stakeholders”; moreover, it “provides the structure through which the objectives of the company are set, and the means of attaining those objectives and monitoring performance are determined” (G20/OECD, 2015).

Therefore, corporate governance is a combination of the structure and the dynamics through which a company aims to best meet the expectations of its shareholders and all other significant stakeholders, such as employees, money lenders, customers, suppliers, communities, and governments, in full respect of mandatory laws, recommendations, and voluntary provisions.

In this regard, corporate governance embodies social responsibility and sustainability principles, which are currently shared worldwide by prosperous businesses of any size. Even in the American scenario, which has traditionally been shareholder-oriented and focused on financial results, large corporations have recently rethought their main purposes embracing a broader perspective. As a consequence, corporate governance now emphasizes a fundamental commitment to all stakeholders, as stated in August 2019 by the Business Roundtable (Business Roundtable, 2019), an association of CEOs of America’s leading companies that has periodically issued corporate governance principles since 1978.

This enriched approach of corporate governance struggles to balance the efforts for generating long-term value for shareholders, who provide the capital that sustains corporate investment, growth, and innovation, with the company’s commitment to all other parties. This requires the equitable composition of economic, social, and environmental interests in corporate objectives, activities, and performances; in other words, corporate governance must be sustainable. That means companies are also expected to take care of their heterogeneous stakeholders. The support to employees through a fair compensation, continuous training, and education and the guarantee of inclusion, dignity, and respect are the core pillars for sound corporate governance in companies operating all over the world. A modern and successful

approach of corporate governance also encompasses dealing fairly and ethically with suppliers, as well as delivering value to customers. Finally, but no less importantly, sound corporate governance aims to contribute to the development of local communities. This can be achieved through the protection of human rights and the adoption of business practices that respect the environment.

Together with the evolution of corporate governance in accordance to sustainability principles, the financial world has witnessed a steady growth in the popularity of ESG-oriented indexes, which track the performance of the largest listed companies with good environmental, social, and governance scores. Stock indexes such as MSCI USA Extended ESG Focus Index, which includes securities across the US equity markets, the FTSE4Good Index Series in the United Kingdom, DAX50 ESG Index in Germany, CAC40 ESG Index in France, and MIB ESG Index in Italy have become increasingly important for investors throughout the world. This underlines the undeniable centrality of sustainability for long-term value creation; in addition, it emphasizes the necessity of implementing structures and processes of corporate governance that ensure the balance of economic, social, and environmental performances, also considering national peculiarities.

A corporate governance structure consists in a company’s system of boards, committees, and officers entrusted with specific powers and responsibilities regarding decision-making, management, and supervision in the interest of shareholders and other stakeholders. In other terms, a corporate governance structure derives from the implementation of a one-tier or a dual-board model of corporate governance.

The distinction between one-tier and two-tier models is indeed a cornerstone of corporate governance laws, regulations, and self-discipline, and it has been largely discussed in the business literature (Hopt, 2013; Jungmann, 2006). The difference between one-tier and two-tier models depends on two elements (Salvioni & Bosetti, 2006):

- The process through which corporate governance boards are appointed, which can require either one or two steps or levels (“tiers”)
- The powers and functions corporate governance boards are entrusted with

The one-tier model is also known as single-tier model or unitary model. The expression “single-tier model” refers to the rules for appointing the persons who will be in charge of administrating the company and monitoring its management: All board members are directly appointed by the shareholders, without intermediate stages. The expression “unitary model” accentuates the attribution of direction and control to the whole board as a collegial body, although these functions are actually exercised by two different groups of directors (namely, the executive directors and the nonexecutive directors). Advantages derive from the unitary nature of the board, for example, rapid exchange of information among directors, better understanding of the company’s affairs, environment, and performance, and fast decision-making (Jungmann, 2006).

The one-tier model is largely adopted in the Anglo-American systems, i.e., the USA and the UK. However, it can also be implemented in Latin European countries (e.g., France, Spain, and Italy), in Scandinavian countries, and in former socialist countries of Europe (e.g., Slovenia, Romania, and Bulgaria), all macroregions where it is either mandatory or allowed by the law.

The two-tier model owes its name to the two steps required for the appointment of its two separate corporate governance boards, i.e., the supervisory board and the management board. The shareholders and, in certain countries, the employees nominate the supervisory board, which in turns appoints the management board. The strong separation of these bodies, due to their different composition, allows us to define this corporate governance structure as a “dual model.” The duality is also evident in the distinctive powers and responsibilities of the two boards. The management board decides and takes part in the company’s day-to-day operations, whereas the duty of the supervisory board is usually limited to overseeing the work of the management board and

assessing the company’s performance. However, the national law or the company’s articles of association can establish that, under specific circumstances, the supervisory board provides the management board with a nonbinding opinion or the formal approval of proposals. In some countries, for example, the management board is expected to consult the supervisory board in relation to strategic and other significant operations.

The two-tier model is primarily associated to Germany, where the legislation and the business tradition recognize the role of labor in corporate governance. According to the laws on codetermination (or “Mitbestimmung” in German), employees have the right to appoint their representatives to the supervisory board. Based on the company’s size and industry, the employee representatives can be as many as half the members of the supervisory body.

Even if codetermination reaches its peak in Germany, employees’ participation in corporate governance is also found in other countries of the Rhine region and Central Europe (Austria, Luxembourg, the Netherlands, and Denmark), Northern Europe (Norway, Sweden, and Finland), and part of the former socialist bloc (Slovenia, Czech Republic, Slovakia, Hungary, Poland, and Romania). In the said countries, there is a clear correspondence between codetermination and the adoption of a two-tier model of corporate governance as imposed or allowed by the national laws. In all likelihood, this depends on the possibility for employees’ representatives in the supervisory board to orientate and control the management board’s activities directly. Furthermore, the presence of employees’ representatives in the main corporate governance body should facilitate dialogue and interaction with the shareholders, a category that often includes banks and other financial institutions. The cooperation among diverse stakeholder classes (i.e., shareholders and employees) within the supervisory board is essential to developing a relationship-based system of corporate governance and to create sustainable shared value in the long term.

Another particular type of dual-board model presupposes the existence of two distinct boards, positioned side by side at the same level in the

corporate governance structure chart and entrusted with different tasks, i.e., the board of directors and the board of statutory auditors. The former is responsible for the company’s direction, which encompasses strategic decision-making and daily management, whereas the board of statutory auditors performs a monitoring function over the company’s administration and information system, verifying their fairness, adequacy, and compliance with the law and the corporate bylaws. The statutory auditors’ tasks can also include controls over accounting and financial statements.

Figure 1 depicts the three different corporate governance models introduced above. Despite their peculiarities, these models present important similarities with each other. Indeed, a path of convergence in international corporate governance has started in this century, particularly after the corporate scandals that involved listed

companies of several countries and the financial crisis that spread throughout the world over the past ten years. Convergence was induced by supranational law reforms (such as those promoted in the EU), self-discipline, and emulation among companies. Even if the process is still underway, it has already determined a significant overcoming of certain substantial differences between corporate governance models, thus making companies more comparable in global markets and contributing to the general improvement of their direction and control worldwide.

Moving from the peculiarities of corporate governance models in some leading economic systems, the following sections aim to reflect on the process of convergence underway, which is currently facilitated by a shared orientation toward stakeholder protection and corporate sustainability.

Author’s own elaboration.
Figure 1 shows the three different corporate governance models that companies around the world can implement. The choice depends on national legislation. In each model, the attribution of powers and responsibilities to one or two boards is defined by the law.

Anglo-American Board Model (One-Tier) Versus European Model (Two-Tier), Fig. 1 Corporate governance models

Outsider and Insider Systems of Corporate Governance

The Cadbury Report of 1992, which represented a milestone in the development of modern corporate governance, defined it as “the system by which companies are directed and controlled.” This raises the question of who must legally be in charge of direction and control within a company.

Several factors have contributed to outline the main features of corporate governance models in each country, although the current trend of convergence is bringing to share some critical elements.

American and British listed companies are usually larger than Latin and Continental Europe’s ones; moreover, they often have a highly dispersed ownership (OECD, 2017). For example, 90% of companies listed on the London Stock Exchange lack a major shareholder owning 25% or more (OECD, 2011). Similarly, US listed companies are rarely under the control of a major shareholder, although important exceptions exist (e.g., Amazon, Facebook, and Walmart) (OECD, 2017). Australia and Ireland, whose business environment is traditionally influenced by the UK, also present a mainly dispersed ownership model (OECD, 2017).

The equity capital of US and UK companies is generally divided among a multitude of small shareholders, each of whom holds a very few number of shares and has little interest in exercising a direct role in the company by taking part in

decision-making, daily operations, and monitoring processes. Therefore, shareholders entrust directors and managers with such functions.

Despite the prevailingly passive attitude of small shareholders, their economic interests find protection in the typical efficiency, transparency, and liquidity of Anglo-American financial markets. Shareholders who have invested in a successful company, whose good performance is reflected in an increased share price, can obtain dividends and capital gains (Rott, 2009), whereas unsatisfied shareholders can easily sell their shareholding on the stock exchange, by opting for the “exit” strategy over the “voice” strategy (which instead consists in intervening and voting in the shareholders’ meeting). Therefore, the financial resources migrate rapidly from a company to another, following the trend of share prices reflecting the perceived soundness of management, as well as the shareholders and analysts’ expectations on future performance.

From the perspective of corporate governance, this situation determines a lack of stability in the ownership of US and UK large companies, as well as in the composition of their boards. A decrease in the share price, combined with the financial markets’ liquidity, paves the way to a takeover; as a consequence, the managers are constantly exposed to the risk of being replaced if the owners change, particularly in case of a hostile takeover (Fig. 2).

The strong power of capital markets in modifying a company’s ownership structure and

Author’s own elaboration.

With reference to an outsider system of corporate governance, Figure 2 shows the implications of corporate performances and related variations in stock exchange price for the board of directors and management. Good performances determine an increase in the share price and strengthen the board and management’s position in the company. Bad performances mean a decrease in the share price, with high possibility for directors and managers to be replaced.

Anglo-American Board Model (One-Tier) Versus European Model (Two-Tier), Fig. 2 Effects of corporate performance

governance is the reason why the Anglo-American business contexts are labeled as “outsider” or “market-oriented” systems.

Another remarkable aspect of the Anglo-American systems is the separation of ownership and control. This separation originates the main issue of corporate governance in large corporations (Berle & Means, 1932), which is known as principal-agent relationship and concerns the alignment of shareholders and managers’ goals (vertical agency problem). According to agency theory, principals employ the services of agents for the latter to perform an activity in behalf of the former; however, principals and agents can have different interests, which lead them to pursue different goals. In a large public company, shareholders are the principals and managers are the agents. Shareholders are interested in long-term value creation and durable growth of the company, whereas managers aim to maximize current cash flows, in order to demonstrate their ability in running the company. Indeed, this will allow them to obtain a higher remuneration, if this is linked to the company’s stock price. To mitigate the risk of misalignment between shareholders’ interests and managers’ behavior and decisions, the agency theory suggests some mechanisms for shareholders to monitor corporate management. In particular, shareholders can appoint nonexecutive, independent directors, i.e., directors who are free of any conflict of interest, to advise and supervise the managers. Today, institutional investors tend to play an increasingly active role in nominating independent directors, who are expected to act with the intent to protect minority shareholders and to promote the sustainable growth of the company in the long run.

By contrast with the Anglo-American outsider systems of corporate governance, the systems used in Continental and Latin European countries are often described as “insider,” “relationship-based,” and “network-based.” These expressions stress the role of insiders, such as controlling owners, banks, and employees, in a company’s decision-making processes, selection of managers, and performance assessment.

Companies from Central, Latin, and Eastern Europe often present blockholders, such as the

founder or the founder’s family, the State, and financial institutions (Amindav and Papaioannou, 2016); blockholders are the owner of majority shareholdings that give him the right to control a company. This concentrated ownership may lead to a horizontal agency issue between majority shareholders and minority shareholders. Majority shareholders have a dominant position in the general meeting and in the board nomination, play an active role in running the company, and have direct access to significant information. By contrast, minority shareholders provide financial resources, in the form of equity capital, but are exposed to the consequences of majority shareholders’ decisions that could expropriate minority shareholders’ wealth (Gogineni et al., 2016). To prevent this risk, the appointment of a sufficient number of independent directors is strongly recommended by the EU Commission (see Sect. 4, Recommendation 2005/162/EC). In some countries, such as Italy, the law also requires the appointment of minority directors, who are elected from a minority list using the slate-voting mechanism.

In Continental and Latin Europe, corporate governance is also affected by the behavior of financial institutions, which hold a large percentage of equity in nonfinancial companies and take active part in the shareholders’ meeting. Suffice it to recall the case of Germany (Hackethal et al., 2005), where banks have long been a prominent actor in corporate governance. The bank-based nature of German corporate governance has a long-standing tradition, which dates back to the last century when the banking sector played a crucial role in overcoming the heavy economic crises following both world wars. Since then, banks have constantly been involved in strategic decision-making and supervision of management in German companies, acting in the positions of direct shareholders and proxy holders representing individual savers.

In the meantime, the banking sector has also continued to provide the German corporations with loans, and this has implied for German banks to assume a twofold role in corporate governance, as both shareholders and creditors. The main consequence is the variety of interests

converging in German companies' supervisory boards. Coexistence of different viewpoints and expectations should stimulate a broad debate within the supervisory board, and in the end, this should lead shareholders and financiers to reach common understanding on companies' strategies and find an agreement on the appointment of the management board.

Among the countries with insider systems, a further distinction can be made based on the so-called codetermination of the board, i.e., the formal participation of employees in corporate governance structures and processes in compliance with the national legislation. Codetermination is a juridical mechanism that recognizes the economic and social relevance of labor as a primary resource for a company's sustainable growth; for this reason, codetermination has been described as a form of workplace democracy (Andersen & Hoff, 2001). Therefore, the laws on codetermination require that a given number of board seats are reserved to the company's employees or their representatives, who are typically elected within the work councils and trade unions. In Europe, codetermination is found in Germany and other Rhine countries (Austria, Luxembourg, and the Netherlands), the Scandinavian countries, and some post-Soviet states where labor participation in corporate governance is a legacy of socialism.

As mentioned above, Germany has the most stringent codetermination system. In fact, the German laws on codetermination ensure an equal representation of shareholders and employees in the supervisory board, at least in large companies.

In the other countries where labor participation in corporate governance is officially provided for by the law, the employees' right to be represented at board level is nevertheless weaker than shareholders'. For instance, labor participation at board level is established at only one-third in the States of the Rhine region other than Germany. In the Northern European countries, codetermination formally exists, but it is applied in each company at the discretion of trade unions, employees, and shareholders. This possibly depends on the fact that in the Northern European countries labor

protection has historically been pursued through important collective bargain actions by highly developed trade unions, which gather the vast majority of workers. OECD statistics on trade union density, expressing the ratio of wage and salary earners that are trade union members, reach very high levels in Iceland (85.5 in 2016), Denmark (67.2 in 2016), Sweden (66.8 in 2015), Finland (64.6 in 2016), and Norway (52.5 in 2015) (OECD, 2018).

In countries like Denmark and Norway, this situation has probably made the need for codetermination less acute, and it has justified the introduction of particular legislative provisions. On the one hand, codetermination must be explicitly claimed by the employees who intend to apply it in the company where they work; on the other hand, a specific agreement between trade unions and the company is sufficient to renounce codetermination, without this infringing the national legislation.

From a structural perspective, the two-tier model of corporate governance is usually adopted to implement codetermination, it being the most appropriate model to support the monitoring tasks performed by the employee representatives over management. However, a one-tier model also serves to this end, when one or more directors are appointed by the employees.

To conclude this section, Table 1 summarizes the key elements of corporate governance in the main Anglo-American and European countries.

A Review of Corporate Governance in Selected Countries

Since the 1990s, a wave of reforms focusing on corporate governance has swept the world, producing its most notable effects on listed companies. Over the past three decades, national listing rules and self-discipline codes based on the "comply-or-explain" principle have frequently dealt with key issues concerning administration and supervision on management. In many countries, recommendations from business associations and requirements imposed by the stock exchanges have even anticipated the introduction of

mandatory provisions by the policymakers. This has certainly contributed to sharing the best practices of corporate governance at the international level and to reducing differences between national systems.

Looking at how listed companies from different countries implement their typical corporate governance models, a clear convergence trend emerges. Listed companies operating in business systems with diverse tradition and attention to shareholders and stakeholders' expectations still present similarities in the board composition and the directors' profiles (Table 2). In this regard, a comparison among the different corporate governance models adopted by American, British, German, French, and Italian listed companies can be useful.

Corporate Governance in the USA

In the Anglo-American countries, listed companies generally implement the one-tier model of corporate governance. The board of directors has a central role in guaranteeing sound and transparent corporate governance. According to the law, a broad range of tasks concerning direction and supervision of the company's business must be fulfilled by the board of directors, who are responsible for creating value in the main interest of shareholders. By contrast, the involvement of the latter in corporate affairs is usually limited to the election of board members and to the discussion and approval of directors' proposals on essential changes such as mergers, sales of assets, dissolution, and amendments to the articles of association and the bylaws.

Despite the collegial nature of the board in US companies, duties are distributed among directors in such a way as to best exploit professional background, education, skills, and experience of each of them in the company, industry, and market. The allocation of tasks also considers individual qualities like impartial judgment and independence.

In US listed companies, the board of directors is commonly composed of both executive and nonexecutive directors. In practice, the board separates direction and control functions, which are performed by executive directors and non-executive ones, respectively.

Executive directors are engaged in the daily management of the company, with the duty to implement the guidelines provided by the whole board. The executive directors have the following responsibilities:

- They must design and develop the company's strategic and financial plans.
- They must outline the organizational structure and flows of information.
- They must select and appoint the corporate officers with whom they will share the managerial tasks.
- They must periodically report to the board about the company's business and performance.

Nonexecutive directors have a monitoring function, consisting in the supervision of executive directors and managers. Nonexecutive directors have a key role in the discussion, approval, and review of the company's long-term plans; furthermore, they can formulate fair and unbiased recommendations on operations and opinions on results, because they are not directly involved in the daily management of the company.

US boards are typically made up of few and yet powerful executive directors. The appointment of a single executive member acting as the chief executive officer (CEO) and the board chair at the same time ("CEO duality") is not even rare. However, effective corporate governance requires balancing powers and responsibilities of each actor, as well as balancing direction and control within the collegial board. For this reason, a large

number of nonexecutive directors is certainly appropriate, and sometimes necessary, to counterbalance a strong CEO. Actually, a significant number of nonexecutive members allow a pervasive and extensive surveillance on the company's CEO, other executives, and senior management, with the purpose of reassuring shareholders that no unfair and opportunistic behavior has been adopted within the board to achieve someone's personal interest.

To improve the quality of advice and supervision provided by the board of directors, the US legislation and listing regulations demand that the majority of board members be independent. In short, it is required that the majority of directors do not have any material conflict of interest with the company, its controlling shareholders, and executives due to family, managerial, business, or consultancy relations.

The appointment of independent directors is also intended to allow a proper composition of board-level committees entrusted with proposing and consultative functions. Such units are totally made up of independent members, and they are devoted to corporate matters that could originate conflicts of interest, such as auditing, director nomination, and director remuneration.

The board also selects a lead director (or presiding director) among its independent members. In brief, the lead director's role consists in (Penbera, 2009):

- Coordinating the activity of all the independent directors and promoting sessions in which they meet without the presence of the CEO and the other nonindependent board members
- Dealing with shareholders' requests and complaints which have not received an adequate answer from the CEO

The current structure of the US boards has mainly been determined by the Sarbanes-Oxley Act (SOX) of 30 July 2002. This Act introduced a mandatory reform of corporate governance as a reaction to the Enron and WorldCom scandals that had come to light in the previous months. By strengthening the rules on director independence, internal controls, and external audit, the US

government aimed to protect the investors from further corporate scandals.

The SOX also marked a turning point for the US governance system toward greater environmental sustainability and accountability. In fact, the SOX has increased the responsibilities of management to implement internal control procedures that should ensure transparent information on environmental costs and liabilities. This is crucial to meet the environmental disclosure requirements imposed by the Securities and Exchange Commission (SEC) to American listed companies (Hall & Pugliese, 2004). More exactly, the SEC Regulation S-K requires a company to:

- Identify any material effects that compliance or noncompliance with federal, state, and local environmental regulations may have on the company's earnings, competitive position, and capital expenditures.
- Disclose any material pending or threatened litigations, including those related to environmental issues, in which the company is a party.
- Discuss and analyze any trends, events, or uncertainties that may have a material effect on the company's financial position; specifically, environmental issues such as GHG emission reduction requirements, proposed hazardous substance restrictions, and expected costs for site clean-up or remediation could qualify as trends, events, or uncertainties affecting the company's financial position.

Although the SOX did not actually change the disclosure requirements mentioned above, it strengthened the responsibilities of management with reference to the adoption of effective internal control processes on both key environmental issues and the accounting procedures to inform shareholders, financial markets, and authorities about their effects on the company's financial results.

Due to its importance, the SOX originated a wave of reforms all over the world, aimed at enhancing independence, integrity, and transparency in corporate governance structures and procedures.

Corporate Governance in the UK

The enhancement of corporate governance in the UK is largely associated to the publication of the Cadbury Report of 1992. However, the original set of recommendations has been revised and enlarged on more occasions, particularly in the last two decades.

According to the UK company law and best practices of corporate governance, British listed companies present a one-tier model that is very similar to the American one. Like US boards, UK boards are based on the division of tasks between executive and nonexecutive directors. UK boards comprise a high percentage of independent members, who are led by a senior independent director, who is a third leadership figure within the board together with the CEO and the chairperson (Hopt, 2013). Moreover, the board delegates functions to three standing committees, which are composed of a majority (nomination committee) or the totality (remuneration committee and audit committee) of independent members. Finally, the UK boards strictly comply with the recommendation of separating CEO and chairperson positions; this is a significant difference compared to what the American companies generally do.

Corporate Governance in Germany

In this century, corporate governance of listed companies has considerably improved in Germany as well. Extensive legislative reforms and a self-discipline code (the Cromme Code, issued in 2002 and last amended in April 2022) have been adopted to enhance shareholder protection and to raise foreign investors' confidence toward the two-tier model and the codetermination system that are peculiar to German companies.

German mandatory provisions on codetermination can be considered as a means to promote stakeholder orientation of businesses by ensuring a balanced representation of shareholders and employees within the supervisory board. Codetermination is regulated by law as follows:

- (a) *Coal and Steel Codetermination Act of 1951*: In coal and steel companies with at least 1000 employees, workers and shareholders elect seven supervisory board members each;

moreover, a neutral member selected by agreement between the two parties has the right to exercise a casting vote in case of stalemate on the board.

- (b) *Works Councils Act of 1952*: In all companies with more than 500 and fewer than 2000 employees, workers have the right to elect one-third of the supervisory board.
- (c) *Codetermination Act of 1976*: In all companies with more than 2000 employees, workers have the right to elect half of the supervisory board (with two to three seats reserved to trade union representatives), whose size depends on the employees' number:
 - Total 12 members (6 elected by the shareholders and 6 elected by the workers) are required in companies with up to 10,000 employees.
 - Total 16 members (8 + 8) are required in companies with 10,001 to 20,000 employees.
 - Total 20 members (10 + 10) are required in companies with more than 20,000 employees.

If the two parties equally represented in the supervisory board do not reach an agreement on the selection of the chairperson and the deputy chairperson, the law establishes that the former is elected by the shareholders' representatives and the latter by the employees' representatives. This rule is crucial, because the chairperson is entitled to the casting vote to resolve a possible deadlock; in other terms, the shareholders can dominate relevant decision-making.

The rules impose the separation between the supervisory board and the management board and establish that the former nominates the latter. Moreover, the supervisory board guide and control the activity of the management board, whose members act as executive directors and may only be dismissed for good cause.

The German corporate governance code contains recommendations to enhance the quality of guidance and supervision exercised by the supervisory board. In this regard, the code states that the supervisory board shall include an appropriate number of independent members, appointed on

the shareholders' side. In addition, no more than two former members of the management board can be appointed to the supervisory board. This recommendation aims at safeguarding the impartiality of judgment that the supervisory board should ensure, but that could be undermined by previous relationships with the executives. Independence is especially important for the supervisory board members who are responsible for monitoring the accounting process and the effectiveness of internal control, risk management, internal auditing, and compliance. Coherently, an audit committee with an independent chair shall be established within the supervisory board.

Corporate Governance in France

The Latin European countries have also seen a significant evolution of their corporate governance systems, induced by a combination of laws and codes of best practices.

In France, where both the one-tier and the two-tier models are permitted by the law, an important innovation has regarded the separation of chair and CEO positions in companies implementing the single-tier structure (Martin, 2017). A reform of 2001 eliminated the previous obligation to entrust the board chairperson with the daily management of the company; since then, this option has been subject to the decision of the board of directors, and the selection of a CEO not belonging to the board has become quite usual.

In the one-tier French model, the board of directors determines the corporate strategies and monitors their implementation; furthermore, it appoints and removes the chairperson and the CEO, determines their remuneration, and supervises the company's operations. Similar powers and duties are attributed to the supervisory board in the two-tier model.

The board of directors in the one-tier model and the supervisory board in the two-tier model can reach a large size, as the law allows up to a maximum of 18 members. In the one-tier model, this rule favors the nomination of nonexecutive directors with monitoring duties.

Participation of employees at board level is also required in state-owned and privatized companies, in companies where employees hold more

than 3% of the share capital, and in companies whose group has more than 1000 employees in France or more than 5000 employees worldwide. According to the circumstances, employees' representation can reach one-third of the board. However, France has no systematic set of laws on codetermination. Corporate governance remains mainly shareholder-oriented, with concentrated ownership in many SMEs and dispersed ownership in a few large corporations.

To promote more equitable corporate governance processes and strengthen minority shareholders' protection, the AFEP-MEDEF code of best practices for listed companies (updated in January 2020) recommends the appointment of independent directors. In companies lacking of a controlling shareholder, half of the board members should be independent; in other companies, one-third of the board should be composed of independent directors. A significant presence of independent members is also necessary to establish internal committees in compliance with the law and the code of corporate governance. Indeed, French listed companies are obliged by law to have an audit committee composed for two-thirds of independent directors, with an independent chairperson and not comprising executive officers; moreover, the audit committee must include a financial expert and an employees' representative. The code recommends the creation of a remuneration committee, which should be mostly composed of independent members, be headed by an independent director, and comprise an employees' representative. Moreover, the board should establish a nomination committee, which should mostly consist of independent members and not include executives.

Corporate Governance in Italy

Italy also deserves to be considered in this review. In fact, it provides the main example of the adoption of a dual-board model in which two separate bodies, namely, a board of directors and a board of statutory auditors, are both elected by the shareholders' meeting. This model is implemented in almost all Italian stock companies, even if they can also opt for either the one-tier model or the two-tier model introduced

by the "Vietti reform" of 2004 (Astori & Bosetti, 2010).

The traditional Italian model ensures strong separation of direction and control, which are assigned to two different collegial bodies: the board of directors, which usually includes both executive and nonexecutive members, and the board of statutory auditors, whose members must be independent from the company's controlling shareholders and executives. The effectiveness of the statutory auditors' activity is enhanced by two additional legal requirements concerning professionalism and honorability of the members.

The board of directors examines, approves, and monitors the implementation of the company's strategic, operational, and financial plans; in addition, it is responsible for running the business. Since these functions are actually carried out by the two distinct groups of directors forming the board (i.e., nonexecutive and executive directors), a further and even stronger separation of management and control characterizes most Italian companies.

The board of statutory auditors performs verifications on the adequacy of the accounting and administrative system; in unlisted companies, it also audits the financial statements.

After the Parmalat scandal of December 2003, which had damaged a multitude of bondholders and small shareholders, Italy issued additional legislative provisions to strengthen corporate governance in listed companies. The "Savings Law" of 2005 introduced the obligation for listed companies to appoint at least one independent director in boards consisting of no more than seven members, and at least two independent directors in larger boards. Furthermore, the law imposed the use of slate voting to nominate at least one director and one statutory auditor representing minority shareholders; the board of statutory auditors must also be headed by a representative of the minorities. Similar rules were also addressed to companies adopting the one-tier model and the two-tier one.

Italian listed companies are also expected to comply with the national corporate governance code, which was first promoted by the stock exchange in 1999 and last revised in January 2020. Among others, the code contains the

following recommendations on the size, composition, and functioning of the board:

- (a) An adequate number of nonexecutive directors shall be independent, and such independence shall be assessed after their appointment, and then on an annual basis.
- (b) A lead independent director should be designated if the chairperson also acts as the company's CEO or is the controlling shareholder.
- (c) The board shall establish one or more standing committees, comprising at least three members. Specifically, the recommendations concern the creation of:
 - A nomination committee, including a majority of independent directors
 - A remuneration committee, made up of nonexecutive directors, in majority independent, and including an expert in finance and compensation policies
 - A control and risk management committee (formerly named audit committee), composed of nonexecutive directors, in majority independent, and comprising an expert in accounting, finance, and risk management

The code of best practices should be applied in all Italian listed companies, with appropriate adaptations if the one-tier model or the two-tier one is implemented.

Summary

We are currently witnessing a growing harmonization of corporate governance throughout the world. This phenomenon is mainly due to the increasing globalization of financial markets, which has induced higher international competition in attracting investments. In this regard, the adoption of the best practices for direction and control can be crucial to raise investors' confidence.

Policymakers, market regulators, and stock exchanges all over the world have continuously issued mandatory and voluntary provisions on

corporate governance, in order to enhance the quality of board activities in listed companies and the protection of minority shareholders. Some leading principles of corporate governance, based on ethics, independence, respect for the law, and safeguarding of stakeholders' expectations, are generally recognized as suitable to achieve these objectives. Therefore, the differences that have existed between country-based models of corporate governance until a few years ago tend to decrease in today's context of market globalization and convergence of companies' behavior.

One-tier and dual-board models have become more similar. Listed companies implementing the one-tier model have progressively introduced a stricter separation of direction and control tasks attributed to the board members; this has certainly been facilitated by the appointment of a significant number of nonexecutive and independent directors, who have been entrusted with the supervision of management. Differently, dual-board models tend to absorb elements which have long been experienced in the single-tier structure, such as the establishment of standing committees. Since matters like director nomination and remuneration, internal control, audit, and risk management have already obtained higher consideration in any business system, they presumably represent the key aspects on which corporate governance practices would further converge in future.

Despite the differences that will continue to exist to some extent (for example, in relation to the CEO duality), a path of convergence is certainly underway. Convergence of corporate governance practices is increasingly involving the business approaches promoted at the board level. In particular, companies all over the world are experiencing a broader adoption of sustainability principles as fundamentals of corporate strategies and operations (Salvioni et al., 2016). This is often accompanied by a stronger orientation to risk management in order to prevent losses and take emerging opportunities. All of this should facilitate long-term value creation, also through a more equitable balance of the economic, social, and ecological expectations converging in every company.

Anglo-American Model vs. Continental Europe Model

Lars Schweizer and Eva Maria Katharina Koscher
Goethe-University Frankfurt am Main, Frankfurt, Germany

Synonyms

Implicit vs. explicit CSR

Definition

Despite the many definitions and the wide use of the *corporate social responsibility* (CSR) term in theory and practice, CSR remains a fluid and somewhat vague concept (Dahlsrud 2008). When it comes to CSR definitions, one should be aware that CSR definitions, as well as CSR practices, differ widely across countries and regions. It should especially be noted that comparative research on CSR in Anglo-American countries and (Continental) European ones identified remarkable differences between company practices on the two sides of the Atlantic (Matten and Moon 2008).

While CSR has traditionally been defined much more in terms of a philanthropic model in Anglo-American countries, the focus in Europe is much more on conducting the whole business in socially responsible ways, complemented by investments in communities for concrete business case reasons (Fernando 2009). In addition, historically, CSR in Anglo-American countries is conducted and communicated more explicitly than in Europe (Maignan and Ralston 2002; Matten and Moon 2008).

History of CSR in the USA and Europe

Despite the wide use of the term *corporate social responsibility* (CSR) in theory and practice, CSR is still a fluid and somewhat vague concept (Dahlsrud 2008). When it comes to CSR, one should be aware that CSR definitions, as well as CSR practices, differ widely across nations and societies (Matten and Moon 2008). This is due to historically grown institutional frameworks that shape national or regional business systems (Whitley 1997). Although all national business systems necessarily consist of individuals and companies, business is conducted in the context of specific social and political environments and national institutions (Moon and Vogel 2008). By definition, CSR assumes an independent company, free to decide how to deploy its resources. But the concept also entails conformance with

laws, which are primarily national in character and scope (Carroll 1991). Therefore, we can observe a considerable variety in the structure and regulation of markets, the involvement of governments and the operation of legal systems, and also when it comes to CSR (Moon and Vogel 2008).

Traditionally, CSR has been seen much more like a desirable philanthropic deed in Anglo-American countries. Companies conduct their business and generate profits unhindered and free except by fulfilling their obligation to pay taxes. Then they donate a certain part of their profits to charitable causes (Fernando 2009). Charitable giving, however, is a complicated and very complex question for any company that has more than one stakeholder (Pearson 2013).

(Continental) European companies do not have such a long tradition when it comes to CSR like Anglo-American companies, but since the European Union started to promote CSR in the early 1990s (see EU communication CSR), many of those companies have adopted a CSR strategy or implemented certain CSR activities. In contrast to the Anglo-American model of CSR, the Continental European model of CSR is much more concerned with operating the whole business in a socially responsible way, complemented by investments in communities for concrete business case reasons (Fernando 2009). In 2011, the European Union (EU) had put forward a new definition of CSR as “the responsibility of enterprises for their impacts on society.” The EU Commission, an important EU institution, has outlined that in order to meet their corporate social responsibility, “enterprises should have in place a process to integrate social, environmental, ethical, human rights and consumer concerns into their business operations and core strategy in close collaboration with their stakeholders” (European Commission 2011).

Fernando (2009) has explained some reasons why it is believed that the Continental European model of CSR is more sustainable:

- (a) Following this approach, CSR becomes an essential part of the wealth creation process

and enhances business competitiveness (if managed properly). At the same time, it will maximize wealth creation for society.

- (b) During challenging times (e.g., during recessions or crisis times), there is an incentive to practice CSR even more and better if it is a core activity. In contrast, CSR activities will be among the first things to go when push comes to shove if it is just a philanthropic exercise with no connection to the wealth creation process of a company.

Explicit vs. Implicit CSR

In their research, Matten and Moon (2008) addressed the question of why and how CSR differs among countries and regions and why and how it changes over time. Arguing in accordance with two schools of thought in institutional theory, the research of Matten and Moon (2008) conceptualizes, first, the main differences between CSR in Anglo-American countries and Europe and, second, the recent intensification of CSR in Europe. Matten and Moon (2008) distinguish between “explicit” and “implicit” CSR: While “explicit” CSR refers to “voluntary programs and strategies by corporations that combine social and business value and address issues perceived as being part of the social responsibility of the company” (Matten and Moon 2008: 409), “implicit” CSR refers to societal values, norms, and rules (both obligatory and customary) which constitute formal and informal institutions. The entry argues that US companies historically had more explicit CSR than European companies. However, US companies’ voluntary CSR programs and strategies are often implicitly covered by European companies due to their legal obligations. For example, labor relations in the USA have been closely linked to CSR since the US government has played a less critical role in supplying welfare benefits to employees and has rarely been involved in wage negotiations (compared to Europe, where governments have historically played a central role in labor market regulation and wage-setting). Therefore, there was comparatively less scope for companies in Europe to make pensions, wages, or health insurance a part of their CSR strategy. These were either supplied

by the government or regulated through laws (Matten and Moon 2008; Moon and Vogel 2008). However, it can be observed that the factors described above are changing over time. In the USA, for example, a growing number of companies are looking now toward core business issues when implementing their CSR activities, and European companies nowadays publish more and more information about their CSR activities, making it more visible and explicit.

Summary

As with any behavior based on collective actions of groups of human beings (as companies are), there is not a “one size fits all” solution. Different norms, values, and priorities will shape business conduct in other countries, societies, or regions. When it comes to CSR, we can observe substantial differences between Anglo-American and Continental European companies. Previous research (Maignan and Ralston 2002; Matten and Moon 2008) has shown that the main differences lie in the fact that Anglo-American companies often conduct CSR activities mainly through philanthropic giving, while in Europe, CSR activities are generally more linked to the core activities of the business and strategic in nature. In addition, Anglo-American companies tend to make their CSR activities more public than European companies do.

Animal Research

► Animal Testings

Animal Testings

Antonio Castrofino
Unitelma Sapienza University, Rome, Italy

Synonyms

Animal experiments; Animal research; In vivo research

Definition

For “animal testing” we mean a scientific test that involves the use of animal testing.

Introduction

The scientific experiments on living beings find a first historical confirmation within the “Corpus Hippocraticum” (end V – the beginning of the fourth century BC). In Aristotle’s treatise “Parts of animals”, we can trace a first attempt at describing the inside and outside of animals by dissection (not of the human being). In the III sec. with the School of Alexandria Erofilo and Erasistrato the human body was studied for the first time by dissecting corpses. In the “Anatomical Procedures” of Galen, the dissection modalities of numerous animal species observed by him (pigs, mice, monkeys) are instead described. Galen also, taking up the idea of the soul of Aristotle, writes “The Usefulness of the Parts of the Body” claiming that the animal in the completeness of its body structure encloses its soul.

Since then, many steps forward have been made, and animal experiments have led to important scientific discoveries and a more in-depth study of the immune system. Revolutionary discoveries were those of insulin for diabetes, treatment for leprosy, yellow fever, and typhoid.

Animal Experiments

Animal experiments can be dual: that of mere observation of behavior and that of application of models to understand a biological characteristic of another species.

After the Nazi atrocities and the Nuremberg trial, experiments on human beings are forbidden, because in the years of the Nazis the atrocities suffered above all by Jews exceeded any ethical limits. The Helsinki Declaration (1964) and the National Commission for the Protection of Human Subjects in Biomedical and Behavioral Research (1974) and the resulting Belmont Report (1979) set the goal of creating protection

about research on human beings by drawing up principles of respect, charity, and justice.

From the principles enunciated in Helsinki, it clearly shows the will to protect the human being.

For this reason, it is emphasized that biomedical research cannot be conducted on human subjects except in cases where the importance of the research itself, and its objective, is not proportionate to the risk to which the human subject is exposed.

This is why more and more often humans have been replaced with animals to conduct more high-risk experiments. Over the past century, however, the question has been raised about the ethics of animal experiments. In particular, the first discussion on this subject was carried out by Charles Hume and William Russell at the Universities Federation for Animal Welfare (UFAW)-tariff in 1957 and was developed by W. Russell and R.L. Burch in 1959 in their book: *The Principles of Humane Experimental Technique*.

Russel and Burch elaborated on the “3R” strategy: reduction, refinement, and replacement.

For the two studies, it was necessary to drastically reduce the number of animals that adjusted for scientific research (reduction). For the animals to which the experimental treatment administered was necessary, during the experiment, the reduction of pain and state of anxiety was triggered by the experiment itself (refinement). Also to this last end, the “sentient” animals considered “superior,” for the two scholars, had to be replaced with “inferior” animals (replacement) (Russel and Burch 1959).

By “replacement” we must mean: “Any scientific method that uses non-sentient material that can replace the use of conscious living vertebrates in animal experimentation.” During the experiments, two hypotheses of “substitution” are considered: absolute or partial with the substitution of the animal or with its partial use without exposure to the problem that could generate stress.

Subsequent studies sought to focus their attention on the understanding of animal sensibility that in the past had not been adequately considered and which today is believed to be more protected (Ferdowsian and Beck 2011). A growing number of studies on the emotion and

cognition of animals have meant that scientists could say with certainty that animals experience pain and anguish.

Stress situations can be triggered by experiments involving invasive procedures, diseases, and deprivation of basic physiological needs. Even the environment in which the animals live strongly affects their quality of life and therefore their well-being. Social deprivation and the loss of natural behavior can trigger a sense of anxiety.

This stress situation also has a significant impact on the result of the research carried out by scholars who often, to achieve a satisfactory result, are forced to use a large number of animals.

As pointed out by W. Lane-Petter in 1958 in his text “Laboratory Animals of High Quality,” although, for equal needs, the work of researchers varies greatly from country to country. The number of research centers and universities is not always the same. The development of the pharmaceutical industry and the investments that each country can make in the sector also greatly affect the quality of the work performed. This means that the number of animals used varies from country to country (Lane-Petter 1958).

Within the development of the animal, tests are inserted a particular type of experimentation that involves the transplantation of cells, tissues, or organs from one animal to another of different species: xenotransplants. These types of intraspecies transplants began in the 1960s and concerned in particular the porcine species and nonhuman primates (Platt and Bach 1991).

We often hear of “genome engineering,” the practice of inserting human genes into the animal gene to produce cells, tissues, or organs that the human body does not reject. We try to study the immunological barrier because it intervenes when a xenotransplant is performed and rejects the organ that the subject has received inside him, considering it foreign to himself.

Another risk factor is the transmission of a pathogen, such as the porcine retrovirus “porcine endogenous retroviruses” or “PERV.”

Further development of animal testing concerns animal cloning. To obtain cloning, genetic manipulation is structured that transfers the somatic cell nucleus (SCNT) of the organism to

be cloned into an egg cell of the same non-fertilized species. An embryo is thus obtained which is implanted in a “surrogate mother.” The first tests already in the 1990s led Ian Wilmut, of the Roslin Institute of Edinburgh in Scotland, to the cloning of the famous sheep “Dolly” (1996).

Also, for this cloning technique is used in animal husbandry to improve the quality of the animals that are raised. Also, for this reason, EFSA, the European Food Safety Authority, has been attentive in the field of food safety and is concerned about the uncertainty of the impact on human health and of animals if cloning is systematically used for food purposes. The European Group on Ethics in Science and New Technologies (GEE) agrees and already in 2008 seemed to express strong doubts about the ethics of cloning animals especially if used for food purposes.

Key Issues

The ongoing debate raises the question of what the limit that science must not overcome in terms of animal tests, genetic manipulations, and xenotransplants. The difficulty of establishing this limit often depends on the sensitivity of individuals and of the civil and religious communities in which this problem is discussed. For this reason, too, this limit often changes according to the state that is analyzed and modified over time.

Future Directions

In the present, and even more so in the future, it will increasingly come to the end of experiments with animals, leaving room for experiments conducted thanks to the use of new technologies. Analysis technologies, computer models, cell cultures, and in vitro, nanotechnology, would help to achieve this important goal. New chromosomal techniques, for example, replace animals in drug dose tests.

Computers, new software, and specialized computer models that can be used and created shortly will increasingly help develop an understanding of biology. Thanks to their use, the

practice of vivisection can cease. Moreover based on various scientific results, especially in branches such as neurology and vascular diseases, there is a question of doubting the reliability of animal experimentation since the same research experiments then replicated on humans have not had the same effects. This is because obviously the same diseases administered to animals do not always imitate the pathological processes and the responses to treatment on humans.

For the study of vaccines, an in vitro surrogate human immune system was also created to obtain surely more reliable results than previous research and, above all, the replacement of animals.

However the overwhelming part of the scientific community, from the members of the Royal Society to those of the National Academy of Sciences, believes that it is not yet possible to totally replace the technology for the use of animals since it has not yet succeeded, even with the most sophisticated models, to totally reproduce a living model.

Xenografts will become important for clinical emergencies and in the absence of human organ donors.

At the core of the ethical debate, these are the following questions: is it right to imitate even cells of different origins within a human body? What is the real limit beyond which science cannot enter by ethical-moral principles?

Cloning has raised an ethical debate concerning its application for the human race. Genetic engineering has placed the study of the human genome at the center of this topic. The ethical debate on the manipulation of human DNA has seen bioethics scholars place themselves in a position of firm condemnation in particular when we speak of “eugenics,” that is, of wanting to modify the characteristics of the human being through such scientific practices. The study and experiments on human embryos are the focus of utmost attention. In many countries including the USA and Italy, these types of experiments are prohibited by law. On the contrary, in Japan much more has been done with the testing of human-animal embryos to obtain human organs suitable for transplants.

Summary

The human being carries out tests on animals to observe their behavior and to understand a biological characteristic of another species. The results of these tests are used by biomedical science in order to always seek new solutions to specific problems, especially of a healthy nature. The tests that take place on animals are often higher risk tests and, after the Declaration of Helsinki of 1964 elaborated by the World Medical Association (WMA), it is not possible to carry them out on humans. The ethical debate that surrounds this topic today is particularly heated because it tries to delineate the limits within which new technologies and sciences are right or wrong to go. Vivisection, manipulation of the human genome, genetic engineering, cloning, xenotransplants, and GMOs are among the most debated topics among scholars.

Definition

Anthropological Sustainability (Morandini 2007) refers to the understanding of practices of social, environmental, and business sustainability not as an end in themselves but rather as parts of a holistic ethical posture. The latter is concerned with public happiness (Bruni and Zamagni 2007; Pabst 2018), spirituality (Zsolnai 2011), and community well-being (Maspero 2020). This perspective builds on the overlapping of theories of Integral Ecology (Esbjörn-Hargens 2005; Jakobsen and Zsolnai 2017; Mickey 2014), Environmental Economy (Musu 2003; Brown 2013), and Economic Anthropology (Carrier 2012), insofar it provides a conceptual framework able to bridge insights from different disciplines working on the issue of sustainability. Anthropological Sustainability collects both religious and secular points of view on the economy of care for the common good. Therefore, it represents a conceptual contribution both to studies on the relations between the individual and the greater good (Zsolnai 2011; Ims and Pedersen 2015) as well as on the interpersonal relations taking place while caring for the common good (Eisler 2014; Zamagni 2008).

Introduction

Anthropological Sustainability (Morandini 2003, 2007) represents a concept able to compel perspectives on social, environmental, and business sustainability by looking at them through the lenses of ethics and anthropology. Economic crises of our time are not circumscribed at the economic system nor can be solved without understanding their broader causes: environmental damage, moral disorder, and political turmoil are interconnected dimensions to be tackled together in order to look for systemic solutions (Ims and Pedersen 2015; Jackson 2010). The popular concept of “sustainable development,” as summarized in the SDGs UN 2030 Agenda, presupposes an idea of a human sustainable development that connects the different goals, in the form of an anthropological idea concerning which would be the limits and the possibilities of

sustainable lifestyles and sustainable societal interactions: indeed, social innovation, throughout all its multidisciplinary contributions, needs to foresee a new model to overcome current crises of the Anthropocene (Moore 2016). Sustainability is a “social construct” concept itself (Bruni 2007, p. 513): it addresses a shared notion of what is desirable, enduring, and meaningful in the long term for humankind as such. Accordingly, Anthropological Sustainability addresses a notion of progress and public happiness way more ambitious than quantified economic growth (Zamagni 2008).

Sustainability is thus a concept developed in the light of peculiar visions of human life as such, i.e., of the anthropological premises underpinning the connected ethical stances (Jonas 1984; Larrivee 2006). As Business Ethics recognizes, anthropological considerations have always shaped the economic and the business sphere: as assumptions, they constitute the basis for economic models built upon them; as understanding of essential features of human kind and of certain cultures, religious behaviors and community habits, they inform the analysis of economic actions (Schlag and Melé 2020; Larrivee 2006). When arguing that sustainable business practices hold a preeminent role, due to their reach and effectiveness, in facing environmental and social crises (Hart 1997), focusing on the anthropological standpoint allows to grasp the nature of this effectiveness: it provides an underpinning theory to practices of sustainability as being connected not only to management of scarce resources and reputational concerns but also to a larger awareness on issues as the quality of life, the idea of justice and of beauty (Morandini 2003). Similarly, recent studies on place-based sustainability management highlight the importance of notions connected to intangible values deriving from places (Shrivastava and Kennelly 2013), thus contributing to shaping a field of inquiry that exceeds economical and technical dimensions, moving toward philosophical and anthropological fields. Ultimately, anthropological sustainability shapes the idea that: “as we know, on the basis of analytical developments of economic anthropology, the partition between ‘market’ and ‘nonmarket’ is fundamentally illusory” (Sapelli 2013, p. 61).

The latter idea entails the possibility to analyze sustainable economic practices (such as, for instance, the theory of the TBL, see among others Elkington 1998, or the adoption of sustainable business models, Stubbs and Cocklin 2008) in the light of a philosophy of integral and multi-dimensional development (Jakobsen and Zsolnai 2017; Alexander 2012) that merge tangible and intangible variables involved.

The idea that “the business of business is the human person” (Melé and Schlag 2015) solicits not only a reflection on what kind of economic system is best suitable for enhancing personal virtue and human dignity but is intertwined with the research on what kind of society would be anthropologically sustainable as well. Anthropological Sustainability is thus influenced by religious spirituality as well as civil mundane engagement toward social justice, in trying to provide answers to these questions. As speculations on the desirable society for human development are phrased by religious intellectuals: “Three Keys Concepts of Catholic Humanism for Economic Activity: Human Dignity, Human Rights and Integral Human Development” (Melé 2015) as well as by scholars involved in the study of relationality and human interdependence and natural sociability (Ross and Creed 2012). Moving from these deeply humanistic perspectives, Anthropological Sustainability represents a useful concept exploitable within the building of the paradigm of Integral ecology: caring for the “common home” (Pope Francis, *Laudato Si'*) is thus conceived not only as a spiritual encounter with the value of the Creation as such, but also as an ethical posture involving the implementation of qualitative relationships between humans and living beings (Zrinyi 2019).

Main Issues

The main issue at stake with Anthropological Sustainability is a thorough understanding of the falsehood of the trade-offs between individual and social welfare, self-interest and solidarity, free market and social progress, human dignity and economic growth, profits and shared prosperity. When facing the grand challenges of our era, such

as economic crisis, inequality, and climate change, scholars and experts have underlined how the individualistic paradigm of short-term maximization not only fosters social disintegration and environmental degradation, but ends up in undermining the very ability of the individual to pursue his/her realization, which is impossible without shared meaning and social recognition (Goldschmidt 1990) and ends up in preventing economic growth as well (among others: Stiglitz 2013).

In this light, Anthropological Sustainability proposes a paradigm able to grasp the proper human distinctive features of economic actions enacted by different subjectivities, organizations, and institutions. For example, when considering pollution and environmental irresponsibility, unlike in the classical view provided by Coase's theory, pollution cannot be considered an externality toward others well-being, but needs to be analyzed throughout a multilevel framework embracing different terrains, all of which are to be involved in the analysis of the consequences of pollution (Esbjörn-Hargens 2005). In this light, integral ecology does not consider only one side of the interaction between business and the environment, such as, in the example, the one that can be monetized, but rather evaluates this dynamic according to the quality of human life, which is at stake because of it (Alexander 2012).

Furthermore, from the disciplinary point of view of economic anthropology, Karl Polanyi explains how an atomized society, whose bounds have been weakened by individualism and pursue of market and economic freedom per se, leads to social turmoil and the request for social protection from economic insecurity addressed to the State; according to this view, individualism leads to a counter-movement balancing the one of the dis-embedding of the economy from society itself (Polanyi 1944). This is one of the most relevant anthropological perspective leading to considerations on how the individualistic paradigm does not conduct to a society of free peaceful individuals but rather to the control imposed by the State on the market that has become *uncivilized*. On the contrary, paradigms such as the one of the Civil Economy, by proposing a positive anthropology,

provide a view of anthropological sustainability for the market, by focusing on its feature of embeddedness within interpersonal relations (Bartolini and Palma 2002). Therefore, in order to argue for the civilized feature of the market, an idea of anthropological sustainability is needed as a requirement.

Anthropological Sustainability provides a field on enquiry that focuses on *how* humans, outside the individualistic paradigm, cooperate and share tangible and intangible values, rather than asking whether they do so. Indeed, as it has been noted: “Interpersonal relationships and individual pursuits both make up distinctive features of human life” (Sison 2017, p. 328). This anthropological standpoint allows to convey the possibility of a harmonious quest for private and common interests that entails the possibility to foresee solidarity, empathy, and reciprocity as ontologically part of exchange relations and, thus, also of economic exchanges (Schlag and Mercado 2016; Zamagni 2008; Sapelli 2013; Davis 1996).

As Anthropological Sustainability understands common well-being as an essential feature of the human condition and as a significant influence over its actions, it goes in the opposite way from the idea of the *homo oeconomicus* and foresees that economic growth can be considered as such only if it bares better off conditions for society as a whole (Zamagni et al. 1999). Mainstream economic reductionism is unable to inquire into the harmonization of individual quests and societal well-being (Grassl 2012). Indeed, experiences of individual and shared prosperity through economic action are increasing and fostering innovative models of making business. The blurring of the boundaries between profit and no profit (Waddock 2014) reveals an increasing sensibility of the contemporary business sphere toward the issue of shared value, strong CSR (Del Baldo and Baldarelli 2015), and Humane enterprise forms of business, able to engage workers and local communities (Mollner 2011; Del Baldo 2020). This trend reveals the possibility of pursuing common good through business organizations not as a general claim but as a concrete set of practices. Consequently, the concept of Anthropological Sustainability is useful in moving from profit-driven agency theory to the notion of prosperity-

driven actions, which is a notion investing the collective sphere rather than the private one alone. Within this approach, the idea of relationality replaces philanthropy in addressing the relation between wealth creation and distribution (Bouckaert 2019).

Ultimately, the understanding of the economic discipline as a moral science (Rona and Zsolnai 2017) presupposes an anthropological stance to be chosen to support consequent moral claims (Bruni and Zamagni 2009). Integral ecology, understood through a dialogue between spirituality in business and sustainable economy, presupposes the overcoming of a conception of development as technologically driven exploitation of resources with short-term objectives and the moving toward a philosophical vision of mutual respect and relational value. Ultimately, Anthropological Sustainability frames integral ecology and integral human development theories by stressing their ability to provide a holistic account of the level of inquiry into the meaning of life as a distinctive feature of humankind and human action.

Summary

Anthropological Sustainability provides a conceptual framework able to bridge the idea of Integral Ecology and Environmental Economy by focusing on both the relationships between humankind and the environment as well as the one in between people caring for the common good and future generations. This idea has a two-fold meaning as it compels both insights from the Catholic Social Thought tradition and insights from economic anthropology, both stressing the idea that there cannot be social and environmental responsibility, accountability, and sustainability without an adequate anthropological background. In this light, inspirations of Integral Ecology taken from Pope Francis’s *Laudato Si’* can be considered common ground for all scholars facing the issue of Anthropological Sustainability: “But one cannot prescind from humanity. There can be no renewal of our relationship with nature without a renewal of humanity itself. There can be no ecology without an adequate anthropology” (*Laudato si’*, §18).

production of aquatic animals and plants (including photosynthetic organisms). Fish is an essential source of protein for humans, and demand will rise as the world's population expands (Tidwell and Allan 2012; Tsado et al. 2012). It is a renewable natural resource that, if carefully managed, may be utilized forever. The present level of exploitation has gone beyond the maximum sustainable output, leaving aquaculture operators to meet the increasing need for artificial production. The process of reproducing aquatic creatures in a regulated or semi-controlled environment is known as aquaculture. According to Dauda and Ibrahim (2015), aquaculture is the cultivation of aquatic creatures with human intervention to increase production while allowing private ownership of the stock produced. The idea of “Blue Farming” aims to increase the sustainability of agricultural lands and farms by assisting in the transition to sustainable and organic farming, while also regenerating the seas, coastal communities, and the climate. The difficulties that fish farmers encounters as they attempt to move toward more sustainable fish production have a natural and circular answer in the form of blue farming (Wouters, 2022).

In contrast to fishing, this enables the selective breeding of species for human food, industrial usage, or recreational fishing. Aquaculture has been critical to long-term fish production. According to Adeogun et al. (2007), it is well-positioned to compensate for declining catch fishing supplies. Jagger and Pender (2001) say that it could make food more secure, cut fish prices, and create new jobs in the fishing industry.

Introduction and Definition

The FAO (Food and Agriculture Organization of the United Nations) defines aquaculture as the

Status of Aquaculture

Since 475 BC, aquaculture has been recorded in China (Cruz et al. 2012). It wasn't until the late 1940s that it was recognized as having a significant influence on spawning by replenishing natural water basins. Since fish capture has been stagnant for more than three decades, the country's existence is dependent on its performance (Dauda et al. 2018). Aquaculture production has steadily grown in recent decades, rising

from a tiny percentage in the 1950s to more than 20% in the mid-1990s. It has progressed from being a secondary to a primary source of fish production in recent decades. According to the FAO (2018), aquaculture produced about 110 million tonnes in 2016, including aquatic plants. The production includes food fish worth 80 million tonnes valued at USD 231.6 billion and 30.1 million tonnes of aquatic plants at USD with 37,900 tonnes of non-food products at USD 214.6 million. This fact proves the feasibility of increasing aquaculture fish productivity. Likewise, exploring global production, Asia contributes to around 89.4 % of global output, followed by the Americas (4.2 %) and Oceania (0.26 %). In 2016, China accounted for around 61.5 % of the world's output (FAO 2018).

Types of Aquaculture

Because aquaculture is done primarily for convenience, there is no standard approach for categorizing it. Because of the wide range of aquaculture operations, describing the many types of aquaculture systems can be difficult. Aquaculture encompasses a wide range of activities, including:

- **Hydrobiological characteristics:** The aquatic environment in which the culture is carried out, such as freshwater, brackish water, or saltwater. Freshwater, which is found chiefly in inland sections of a country, and saltwater, found in seas and oceans, have vastly different salinities, ranging from zero to nearly 35 parts per trillion in the former and nearly 35 parts per trillion in the latter. Brackish water is in estuaries, river deltas, lagoons, and backwaters worldwide, subject to tidal forces. The salinity in such ecosystems varies greatly, from insignificant to 35 parts per thousand, depending on the tide phase and the volume of freshwater discharged into the sea through the river. Finfish and shellfish found in brackish seas are always euryhaline, meaning they belong to a group of organisms that can endure large fluctuations in salt in their environment. Aside from the salt of the water, the temperature of

the water has a selective effect on the fish that flourish there, such as warm-water fish against temperate or coldwater fish. Coldwater fish, e.g., trout, loach, etc., can be found in temperate countries and the higher reaches of tropical countries at high altitudes. Then there's the particular fish fauna of warm waters, e.g., scores of carps and catfishes and several species of mussels, etc.

- **Water exchange** Aquaculture systems come in various types, despite variances in the physicochemical features of their habitats. The amplitude and intensity of water exchange rates in most systems vary. The volume of water exchanged, or the control over water flow to the system is called water exchange. Water exchange levels are static, open, semi-closed, and recirculating (closed). Pond culture is used in a lot of aquaculture operations around the world. During the culture stage, there is no water exchange in these ponds. To compensate for evaporation, some topping up may be necessary. When a cage system is situated within a large body of water, such as an ocean or an estuary, it is described as an open system. The fish in these cage systems are usually kept at a high density, and artificial feed is provided. On the other hand, natural currents and tides keep water quality in check. As a result, these are open systems that require a lot of work. Globally, cage-based fish production is rising, and the technologies are now well developed in Europe, sections of South America (mainly Chile), and China. Recirculating systems typically have extraordinarily little water exchange during a production cycle, hence the term "closed" systems. Particulate matter is filtered out of the water as it runs through the treatment chamber, and the air is added. This closed system regulates salinity, temperature, oxygen, and other variables. It is a green system since just a tiny amount of new water is released to replenish the water that has evaporated. In most recirculating tank systems with intensive culture, some water is drained and refilled each day. This situation is due to parts of the routine maintenance procedure for nitrate removal.

- **Intensity of culture:** This indicates the number of aquaculture organisms per unit area or volume of water and the system's ability to support biological productivity. Depending on its intensity, culture is classified as intense, semi-intensive, or extensive. Intensification aims to increase yield while using the same or less land, water, and labor inputs. The following concepts guide these systems: (1) Increase water flow and pond aeration to provide oxygen to the pond. (2) Protein-rich pellets are fed. (3) Increasing the number of fish species stocked.
- **Fish farming methods:** This refers to the number of different fish species that are raised in the same pond, such as monoculture, polyculture, or integrated farming. Monoculture is the cultivation of a single species of organism in any sort of water, fresh, brackish, or salt. Whereas polyculture is the cultivation of multiple species in a single body of water. Integrated fish farming is raising fish in conjunction with other agricultural/livestock operations in a pond. The farming sub-systems, such as fish, crops, and livestock, are intertwined so that byproducts/waste from one sub-system become valuable inputs to another, ensuring total land usage. This combination of intensity, culture methods, species, farming techniques, and distinct phases of culture results in a highly diversified set of aquaculture systems and technology.

Aquaculture Species

Finfish, crabs, mollusks, other aquatic invertebrates, and aquatic plants have all been successfully farmed by humans. Although the exact number of current fish species is unknown due to discoveries regularly, Nelson (2006) estimated around 515 families and 32,500 marine and freshwater fish species (Helfman et al. 2009). Not all of these fish species can currently be raised in captivity. Aquaculture candidate species are defined by their hardness, rapid growth, resilience to disease and parasites, ability to reproduce in captivity, tolerance to artificial feeding, and market

availability. These are some of the most important characteristics that distinguish a species as a prospective aquaculture candidate (Ajani et al. 2011). According to the FAO (2018), over 598 aquatic animal species have been or are currently being economically farmed. Fish account for the majority of the species (369), followed by mollusks (109), crustaceans (64), amphibians and reptiles (7), and aquatic invertebrates (9), and maybe 40 algae. The silver carp (*Ctenopharyngodon idellus*) is native to Southeast Asia. *Hypophthalmichthys molitrix* is a kind of carp. *Cyprinus carpio* and Nile Tilapia are two of the most common freshwater fish. Bighead carp and *Oreochromis niloticus* are both African carp species. *Hypophthalmichthys nobilis* is the most commonly farmed finfish. The legs of whiteleg shrimp are white. The most commonly farmed species, *Penaeus vannamei*, accounts for more than half of all farmed crustaceans. A cup of oysters, *Crassostrea spp.*, and *Ruditapes philippinarum* are the most farmed mollusks, whereas the Chinese softshell turtle, *Trionyx sinensis*, is the most extensively farmed aquatic animal.

Precision Aquaculture

Precision aquaculture is a technique for increasing fish farmers' ability to check, regulate, and record biological processes in aquaculture production. Precision aquaculture is helpful when considering fish farming in four cyclical operational processes: observe, interpret, decide, and act. First, the farmer sees and records the fish's bio-reactions, either by hand or using data-gathering technology such as cameras. The farmer then subjectively examines this data to acquire a real-time picture of the fish's health. Agricultural operations and management choices are created based on these interpretations, then manually applied in the cage. Precision aquaculture techniques use technical solutions and notions of automation for several or all areas of agricultural operations. Thereby converting operational features associated with various fish farming operations from an experience-based to a knowledge-

based regime. Improve agricultural activity accuracy, precision, and repeatability; enable more autonomous and continuous biomass/animal monitoring; give more reliable decision support, and minimize reliance on manual labor and subjective judgment, increasing staff safety. Animal health and well-being will improve because of precision aquaculture. This situation will also improve yield and output and the environment. There are technological constraints in a fish farm setting due to the underlying physics of the sub-surface environment, sensor technology characteristics, and data transmission protocol restrictions. These challenges must be overcome before a complete shift to commercial aquaculture occurs. Changing system settings, adding new product features, and moving equipment are practical options.

Infrastructure and support technologies are also critical. Among the difficulties relating to infrastructure and support, technologies are those relating to environmental evaluation and planning, such as computerization of aquaculture production, financial commands and control, systems to assist in decision-making during planning, farm management software that is more effective also improved online monitoring devices, as well as dependable calibration and self-diagnosis are required (for biomass, environmental parameters).

For adequate better zoning and control, as well as improved environmental management include incorporating Geographic Information Systems (GIS) into System Management, improved approaches for impact evaluation — for example, carrying and holding ability models — might be beneficial, and vaccines and parasite treatments are applied in enormous quantities across producing zones.

Issues Affecting Aquaculture

Many of today's aquaculture practices are environmentally hazardous. In aquaculture, eutrophication is a prevalent problem and refers to an environment's excessive nitrogen and phosphorus enrichment. Aquaculture uses antibiotics, which leads to eutrophication. Excess fish feed

introduces significant levels of nitrogen and phosphorus into open-water aquaculture systems (Talbot and Hole 1994). Closed inland systems that dump wastewater straight into natural rivers may lead to eutrophication (Talbot and Hole 1994). Unexpectedly, ecological aquaculture pollution has occurred from a rapidly expanding and poorly managed industry. Aquaculture waste adds to nutrient contamination and harms other fish. Aquaculture methods like open net-cage farming are often utilized around the borders of large bodies of water. It is hard to escape feces into the sea where farmed fish are trapped in large mesh fishing nets. Antibiotics, insecticides, and fish excrement may be included in this waste, rendering it inappropriate for human eating, recreational use, or animal survival.

Overfeeding of Fish and other marine organisms can affect the environment. A lack of control and a faulty feed plan may have a wide range of adverse environmental consequences. Nutrients that have not been utilized are released into the environment, causing the ecosystem to adapt to survive. Aquaculture waste discharged into the environment also harms the ecosystem. Aquaculture, like all other methods of animal production, generates waste. Aquaculture solid waste is classified into solid waste and dissolved waste (Amirkolaie 2011). Uneaten or spilled feed and fish excrement are examples of solid waste. The majority of dissolved waste is assumed to be caused by fish metabolites (Amirkolaie 2011). These two pollutants build up in a system and eventually deteriorate water quality, leading to an invasion of disease-carrying fish. Aquatic systems such as ponds, raceways, and caged systems generate artificial channels by continuously pumping water through them. This system allows the system to maintain a higher level of water quality for the fish. It also shows that dissolved and solid wastes are released into the environment regularly and unreported (Martins et al. 2010), which means that they don't get cleaned up.

The ongoing improvement in feed digestibility (which allows fish to eat more nutrients while producing fewer waste products) has lowered organic waste and operating costs (Bureau and Hua 2011). Fish, like other livestock, may be

carefully chosen to improve their “feed-conversion ratio” (i.e., the kilograms of feed needed to produce one kilogram of product). New farming approaches are now being tested. The production of shellfish and seaweed close to or alongside finfish farms has been suggested to reduce nutrient pollution. IMA, or integrated multi-trophic aquaculture, is becoming more popular as a workable alternative to traditional aquaculture practices. Fish meal and fish oil are essential components of aquaculture feed. Because of this reliance on fisheries, overfishing and overexploitation of natural aquatic resources occur. Despite extensive investigation, no commercially viable alternative feed components have yet to be discovered.

Similarly, cultured Fish release nutrients caused by cultured organisms' eating and excretion (uneaten food and waste products). Therefore, it causes organic enrichment and lowers oxygen levels, and increases animal mortality. These result in dead zones and significant changes in the benthos, the biological communities at the bottom of aquatic environments. The discharge of organic and inorganic nutrients then further from microalgal blooms (eutrophication) alters the aquatic food chain.

Invasive species are becoming a global problem. Many aquaculture organisms are unusually adapted to their habitats. A notable example is the culture of Atlantic salmon (*Salmo salar*) in Chilean fjords. Invading species introduce new diseases into natural populations (parasites and pathogens are imported into the aquatic environment). The species that live in open water sometimes go extinct due to failure, human mistakes, or harsh weather. There is more competition for food and space when invasive species move into an area where they are not native. This factor can hurt the health of the animals and plants there.

Aquaculture is so poorly regulated at the state, national, and international levels that it endangers the natural environment we humans rely on and enjoy. Algal blooms are one of the most dangerous and difficult-to-control effects of fertilizer runoff. This kind of algae bloom is harmful to both humans and animals, and it has the potential to interrupt daily routines. These blooms can

make local water unsafe for drinking and recreational use and damage native creatures. According to experts, aquaculture in its current form endangers our natural system. Aquaculture regulation may result in enhanced human food products and economic advantages from job creation in various businesses. It may also be beneficial to the environment.

Strength and Benefit of Aquaculture

Globally, there are now more than 7 billion people, with projections of more than 10 billion by 2050. Despite significant advancements in food delivery, the World Food Programme predicts that 800 million people will be hungry by 2020. The SDGs call for increased food production, the development of resilient and sustainable food systems, and the provision of safe and nutritious food to everyone. The “Blue Revolution” has piqued the public's curiosity. As a “rich dinner for the poor,” fish is ideally positioned to aid in achieving the SDGs. Because most fish populations have been fished to their total capacity or at unsustainable levels, the seafood industry has shifted to aquaculture, which has risen dramatically in recent decades. Aquaculture provides food and livelihoods, but it also helps to rehabilitate fragile and endangered species populations and increase wild stock numbers. People who work in seafood processing, feed, and equipment production get jobs because aquaculture helps them.

While food security guarantees that everyone has access to nutritious food and enough calories, the significance of aquaculture in supplying healthy, lean protein to the world's expanding population cannot be overstated. Aquaculture also helps to ensure the food security of many low-income individuals in developing countries. It is estimated that they account for 22% of total animal protein intake in food-insecure countries. Experts recommend that pregnant or nursing women, as well as children, consume seafood. Consumption of farmed fish may improve nutrition and food security for many individuals.

Diversification in aquaculture is owing to the continuous introduction of new species and activities. There is a solution for you, from small-scale inshore to large-scale (industrial) offshore aquaculture production systems. Diversification is critical for resilience to climate change and other external pressures, regardless of the sector's diversity of species, production zones, and artistic techniques – whether in marine or freshwater settings. This variety safeguards aquaculture food systems against economic, social, and environmental threats. The use of more climate-resilient species and genetic strains may reduce the sector's susceptibility to climate change.

Further north, Atlantic and Cod output is increasing, while Halibut and Sole are becoming more popular with buyers. Diversification is becoming more common among freshwater farmers, with the cultivation of Sturgeon for both caviar and meat being the most well-known example. Several catfish species, including the Wels catfish and the African catfish, are being researched.

As a result, freshwater scarcity has become a worldwide concern. Competition for freshwater resources is developing among aquaculture and other users, such as agriculture, which uses more than 70% of the world's freshwater. It is difficult to increase food production through efficient water use. The recirculatory aquaculture system (RAS) is critical to our food chain's ability to adjust to climate change. The water is filtered before it is recirculated back into the system, which removes metabolic waste from the stock. Mechanical or biological filtration, sterilization, and oxygenation are used to purify water. Water reuse varies in complexity and efficiency, but all RAS reuse water to a high degree (> 90%). RAS technology has significantly improved in the last two decades, and its popularity has recently expanded. RAS uses Biofloc technology to conserve even more water. Probiotic nutrients may assist fish in developing faster, responding better to antibiotics, and reducing oxidative stress. The status and relevance of aquaculture are projected to expand in the next few years as worldwide consumer demand for healthy food rises.

Marketing of Aquaculture Products

Market-based fish and aquaculture products will be found and produced, with commercialization being vital to the success of an aquaculture firm. A profitable fish farm can be created using the four Ps of marketing: Place, Price, Product, and Promotion. Fishers who want to make money need to know about popular fish species, marketing channels, target markets, government regulations, and set prices. They are identifying a target audience or customer, whether merchants, shop owners, wholesalers, restaurants, or local fishmongers, to help decide what to market. In addition to their commercial potential, although acceptability varies by region, highly sought-after aquaculture species should be farmed or marketed in varieties to offer farmers a competitive edge. Extensive but straightforward market and customer preference surveys may aid in resolving the product form problem. Customers would be willing to pay more for their benefits, and producers would understand how to promote their products and where to find individuals in need. The next step is to create unique marketing methods to persuade buyers to choose the firm over competitors. Farmers' marketability and reach will expand due to price decisions, marketing initiatives, and healthy eating programs. Improvements to the supply chain and logistics and government certifications to encourage healthy eating will boost agricultural sales. Customers are more likely to purchase a product if they believe it is readily available and appropriately priced. According to Burnham and Leary (2018), word-of-mouth marketing is the most effective form of advertisement. Customers that get exceptional customer service are more likely to recommend it to their friends and family and return to the company. However, customers who get defective fish products may question the producers. Fish products may be promoted through social media, radio jingles, local magazine advertisements, and cooking shows. However, everything must be precise and concise. It will also provide raised fish producers with a competitive advantage.

Aquaculture is a long-standing yet highly competitive commercial sector. Inland fishers,

trawlers, other farm-raised fish producers, and animal producers compete with fish farmers. Knowing your competitors' strengths and shortcomings may help you develop marketing tactics that can endure the rigors of manufacturing and distribution. Aquaculturists must acquire information, energy, and resources about their sector to evaluate their competitors. These rules, if followed, will assist in the profitable sale of aquaculture items.

Perseverance is rewarded in this life. A successful aquaculture company must have a well-thought-out business and marketing plan. Time, effort, and innovation are necessary inputs in the fish marketing process. Producers should look at and work on each idea independently, keeping their budgets and resources in mind.

Sustainability of Aquaculture

Aquaculture production has grown by twelve in the previous 30 years. As a result, it is responsible for meeting the world's rising need for fish protein in an environmentally beneficial manner (HLPE 2014). It can supply jobs for the world's growing population, particularly in underdeveloped countries. However, it must incorporate environmental, economic, and social sustainability to be sustainable. The kind of fish cultivated, the location, environmental constraints, and the skill level of the fish farmer all affect the construction of a sustainable aquaculture system. Aquaculturists are being pushed to grow in an environmentally sustainable manner. Environmentalists believe aquaculture is unsustainable because of the negative environmental repercussions and eutrophication of fish-producing water bodies (Bill 2017). Meanwhile, sustainable aquaculture activities must not be considered adequate to affect the biodiverse fauna and flora. They support the effective use of value-added fish products, waste reduction, sludge, organic matter, and filtering process management. Wastewater should be treated, recycled, or managed before being released into the environment. The preservation of a circular and cooperative economy is critical for efficient farming and business operations. The

organization places a premium on biosecurity, accountability, decreasing synthetic fertilizer and pesticides, and supporting correct financial records. Polyculture, cultivating water creatures alongside terrestrial plants or animals, may effectively use multiple niches and resources within the farm with low output and bring mutually beneficial advantages to the species grown while boosting the farm's economic performance. A long-term aquaculture industry with long-term aims and prospects is required. Fishers must adhere to legal requirements while embracing effective and safe community practices. The well-being of the community should come first. If you work in agriculture, no matter your race or gender or how much money you make, your job should be safe and paid fairly. Well-managed aquaculture will give significant advantages while creating minimal harm to the ecosystem over time. A new management plan that incorporates the implications of aquaculture on ecosystems and actions that are predictable, tolerant, robust, and adaptive over a wide variety of locations is necessary to boost the sector's production and sustainability. It is required to educate local communities, industry, and other significant players about impact assessments and procedures for creating a regulatory framework. Increasing coastal preservation is critical for the long-term sustainability of the ecosystem and future food security. This situation includes better management and conservation of natural resources and the promotion of environmentally and economically sound aquaculture (Gomez 2020).

Summary

Aquaculture's rapid expansion has made it a critical source of human nutrition and a contributor to global food security. Long-term aquaculture development needs ecological integrity. An innovative, integrated, and multi-disciplinary approach to aquatic resource management attempts to collect as many ecological products and services from seas, rivers, and wetlands as possible while also supplying social and economic benefits. It strives to decrease poverty,

hunger, and malnutrition by incorporating inclusive growth management. It is becoming more necessary for society to develop the economic capability to sustainably use aquatic ecosystems and their benefits in the blue economy.

Definition

Environmental sensitivity is a warning to society that, if no action is taken soon, the world as it has been known could be degraded to such extremes that could never have been imagined. However, this is not a future alert as there are painful examples in the immediate present of how the human hand is capable of transforming the face of the planet. In this sense, the Aral Sea disaster serves as a model to epitomize the nefarious repercussions of short-term economic policies on the natural habitat. The Aral Sea disaster and what it entailed are detailed below: the conversion of a lake into a desert, the sudden change in the geography of the area, the disappearance of millenarian native cultures, the exposure of the population to pollutants of all kinds, the bacteriological war, or the emergence of several diplomatic conflicts between those countries with economic interests in the lake basin that still do not agree on what decisions to take, once the damage to humanity seems to be irreversible.

Introduction

Something very strange must be happening if during the last few years dust particles fall on Norway and Greenland from a remote desert located several thousand kilometers away, which in turn is settled on the floor of what became one of the largest lakes on the planet until only 60 years ago (Pandey and Jha, 2003). This desert (Aralkum) extends over most of the ancient Aral Sea, in what is one of the greatest environmental catastrophes in the history of mankind, which, despite all attempts, seems to show very difficult or impossible solutions. While other environmental tragedies such as the Exxon Valdez oil spill, the nuclear disasters of Chernobyl and Fukushima, or the Bhopal accident did have a huge media impact since they occurred, this catastrophe was initially hidden, hence it is usually recognized in the literature as “Quiet Chernobyl” (Kumar, 2002). Its magnitude would become known when in the early 1990s A. Gore, then vice president of the USA, related his feelings of helplessness and disbelief in the face of the sinister image of the merchant ships stranded in the dry bottom of the Aral Sea (see Gore, 1992), an icon that would gradually transcend among the international public opinion after the fall of the Iron Curtain.

The motives that prompted this “Man-Made Desert” could not be specifically assigned to any particular person or human group but to the greed and thoughtless short-term policies (Breckle and Geldyeva, 2011; Joger et al., 2011) or perhaps to the *Gossypium*, that is, to the cotton. Effectively, this small plant, just as it was the involuntary protagonist of the slave trade in the Americas, was also the main character of everything that happened in the Aral Sea. The purpose of this entry is to summarize what was this environmental calamity, its genesis, as well as a series of facts of great relevance that were concatenated from it. If there is a lesson to be learned from any event that threatens the ecosystem, the Aral Sea Disaster is probably one of the most noteworthy, as it demonstrates that respect for the ecosystem is more than a mere motto: it must be a civic obligation.

Geopolitical Context of the Aral Sea

The vast area around the Aral Sea was already populated during the Neolithic period by several hunters and fishing tribes (Breckle and Geldyeva, 2011), with its first purely historical reference appearing in Strabo which places it “behind *Tanais* and *Meotide*” (see Zonn et al., 2009). Centuries later, Emperor Wu of Han sent the Chang-Ch’ien emissary to establish diplomatic-commercial relations with the tribal clans of the area, and from this expedition the first available data on the lake. In the second half of the nineteenth century, the Russian conquest of Central Asia took place, being later this enormous territory split during the Soviet era into two Soviet Socialist Republics: Kazakh and Uzbek (today Kazakhstan and Uzbekistan). It was from the 1950s onward that the problems in the Aral Sea really began, as a consequence of Soviet developmentalist policies which proved to be somewhat effective but which, under no circumstances, could be considered respectful of the environment or the most elemental human rights.

In effect, the drying of the Aral Sea can be contemplated as the most important “achievement” carried out by the ancient Soviet authorities in order to ensure maximum five-year production quotas, whatever the cost: economic, human, or environmental. Along with this catastrophe, it may be listed a long number such as the erection of the Stalingrad/Volgograd Hydroelectric Power Station, the construction of The Karakum Canal, or the cruel *Holodomor* (1933), a time when practically all Ukrainian wheat production was confiscated, with which more than 3 million human beings died of hunger (Wolny, 2017). With a few exceptions such as Kelley (1976), it must be taken into account that the existing sources on this catastrophe, or any critical monograph on the environmental subrogation to the Soviet corporate productivity, are practically nonexistent due to the censorship exercised by the *nomenklatura* since it was not until February 1986 that M. Gorbachev enunciated the mythic phrase “restructuring and transparency” (*perestroika* and *glasnost*) on the occasion of the 27th Congress of the CPSU. Certainly, from this openness onward some measures

began to be taken to counteract the environmental damage; however, they were either insufficient or it was too late (see, i.e., Pryde, 1988; DeBardeleben, 1990).

Genesis, Evolution, and Consequences of the Aral Sea Disaster

The Aral Sea has always been considered the fourth largest lake in the world after the Caspian Sea, Lake Superior, and Lake Victoria, but it has seen its flow reduced significantly to 10% of what it was in the 1960s. Despite its name, the Aral Sea has no outlet to the sea as it is a closed or endorheic basin (Micklin, 2016) and is fed by two rivers that cross Central Asia: Amu Daria and Sir Daria, born in the western anteroom of the Himalayas (Thiam Sam and Pamir mountains). The total area of the lake basin covers 1,200,000–1,300,000 km² extending over Northern Afghanistan, the southern part of Kazakhstan, a large part of Turkmenistan and Kyrgyzstan, and the whole of Tadjikistan and Uzbekistan (Ivanov et al., 1996). The course of both rivers was diverted in the 1950s to increase the cotton monoculture in the area, which is why the Karakum canal (about 500 kilometers long) was built with the sole idea of enlarging the irrigated area. However, this engineering work turned out to be really inefficient and wasteful, since up to 70% of the water transported was lost, although the objectives initially set were achieved, since Uzbekistan became one of the first cotton producers in the world and, consequently, the Soviet Union was able to show off its cotton production against the USA, its antagonistic rival during the Cold War.

Those economic successes had dire consequences for the Aral Sea, verifying the proverb “bread now, hunger for tomorrow”: The lake passed from an initial extension of 68,000 km² in the 1960s to less than 7,000 km² in the 1980s, becoming even smaller than the Titicaca Lake.

From the beginning, the Soviet authorities were aware of the coming disaster, but instead of stopping it, they chose to do just the opposite, blinded by their greed, i.e., to drain the lake further, in order to obtain more cultivable lands for

cotton production. In this way, the traditional fishing industry in the area, which along with the Caspian Sea supplied the entire Soviet Union, was practically reduced to a minimum. Note that this was always the main economic resource of the regions near the lake, so the socioeconomic impact was terrible because some local populations that were on the verge of disappearing impacting negatively on the ancient sociocultural idiosyncrasies of the area. Table 1 summarizes the most representative species of fish in the lake, obviously affected by its gradual disappearance over the last 60 years:

From 1987, the decline in the water flow caused the lake to split into two parts: the northern part in Kazakhstan (North Aral Sea or “The Small Sea”) and the southern part in Uzbekistan (South Aral Sea or “The Large Sea”), which marked an even faster decline in its surface, hence the UN

came to consider it the greatest ecological disaster on the planet deliberately caused by the human hand (see i.e. Grabish, 1999). Figure 1 details how the main indicators of the Aral Sea varied between 1966 and 2009:

Inevitably, the climatic consequences began to take effect: The water surface constituted a factor that counterbalanced the extreme temperatures of the region, so that its loss led to much warmer summers and especially cold winters, with periods of prolonged and persistent droughts occurring very frequently. In the same way, salinity reached 100 grams per liter, much more than in the oceans themselves.

This phenomenon was aggravated by the use of a wide variety of highly toxic components such as heavy metals, pesticides, fertilizers, and poly-aromatic hydrocarbons (Ivanov et al., 1996) that had been intended for cotton cultivation. Consequently, Waehler and Dietrichs (2017) pointed out that the infant mortality rate in and around the Aral Sea is significantly higher than in Uzbekistan or Russia, with abnormally low fertility rates and body mass indexes compared to other nearby countries in the same area. It is worth noting that the events on Vozrozhdeniya Island summarize the ongoing nonsense that the Aral Sea was facing: The sudden reduction of the waters turned the island into a peninsula (sarcastically, “Vozrozhdeniya” in Russian means “rebirth”). In 1948, a top secret biological weapons research base was established there (Aralsk-7), where it seems that among other bioagents tested were: *Botulinum toxin*, *Brucella suis*, *Coxiella burnetii*, *Francisella tularensis*, *Rickettsia prowazekii*, *Variola major*, *Venezuelan equine encephalitis virus*, and *Yersinia pestis* (see Bozheyeva et al., 1999). This base would later be abandoned, but in 1971 an accident known as the Aral smallpox incident occurred in which part of the population of the area was severely affected by an outbreak of smallpox derived from those infamous tests. Faced with this situation, after the fall of the Soviet bloc the countries most involved in the problems that arose after the drying up of the Aral Sea had to take action, so in 1992 they created the International Fund for Saving the Aral Sea (IFAS). Among other measures, it was

decided that each country would allocate a proportional part of its national budget to restore all the problems that had occurred, but this collaboration was left in the middle of the agreement insofar as the economic interests of the signatories of the agreement were totally opposed. For example, of the five nations involved, Kyrgyzstan and Tajikistan have no oil or natural gas reserves, so they installed hydroelectric power plants at the headwaters of the Amu Daria and Sir Daria rivers, resulting in the situation not improving, as much as the flow of these rivers was once again limited. Fortunately, there has been a minimal recovery of the water flow in the northern part of the lake (Kazakhstan) since the construction of the Korakal Dam in 2005, a structure cofinanced by the World Bank.

This mega containment system is named after the Korakal peninsula which, like the Vozrozhdeniya peninsula, was once an island. Its entry into service has enabled the waters of the Sir Daria river to be contained in the northern part of the extinct lake, which has made it possible for the desalination of the waters to begin to decline in that area (see Fig 1), the watercourses to rise again

and, therefore, the coastal populations to return to the shores of the lake. However, this project also has its limitations, as it involves safeguarding the northern part of the lake at the expense of what little is remaining of the southern part.

Summary

Although the Aral Sea is a “young” lake in geological terms (Joger et al., 2011), it has only taken 60 years to destroy what nature built 35,000 years ago. This entry obviously shows how the interrelationship between irrigation and drainage (Bos and Aart, 2012) are the main causes of the Aral Sea disaster, but it also contains an implicit message: Large-scale public works such as those in which the decision to drain the Aral Sea was made should never be left to countries or institutions with democratic deficits (Pandey and Jha, 2003) as was unequivocally the case in the Soviet Union in the 1950s and 1960s. Not without some reason, the capitalist system today is judged to be unscrupulous and, to a certain extent, is advocating the establishment of production models similar to

those of the former Soviet Union, when these systems were precisely characterized by the systematic violation of the environment.

If it were not for the supervening seriousness, the Aral Sea catastrophe could be seen as a surrealist tragicomedy: boats and trucks stranded in the middle of a desert, islands that appear and disappear and become peninsulas, towns that were coastal 60 years ago, today remain far from the lake for many kilometers. This spectral panorama does not belong to another world, but this one, and represents a clear warning of what can happen again at any time and place if the right decisions are not taken.

Definition

“Arms export” means the sale of arms made by producing countries to buying countries.

Introduction

In the centuries that saw the ancient civilizations and the great peoples (Egyptians, Greeks, Persians, Romans) flourish, the birth of the warrior figure and subsequently the formation of the organized army led to the first phase of strong investment by the rulers in military spending.

In the following centuries, the invention of ever more lethal weapons led to an advancement in the art of war. In the transition from the Middle Ages to the First World War, the war was transformed from a siege war to a war of attrition. The two industrial revolutions led the companies of the eighteenth and nineteenth centuries to a

standardized production that until recently was mostly handmade.

The two great world wars saw a development hitherto unthinkable of the armaments production system. The atomic bombs dropped on Hiroshima and Nagasaki were the culmination of centuries of development and the first real moment of reflection on how much the human being could harm himself. The UN was born in 1945 to maintain world peace and promote disarmament.

The “Cold War” saw, after the Second World War, the USA and the USSR protagonists in a very high international tension which only out of a sense of responsibility on both sides did not result in a nuclear conflict.

Today, the greatest attention is paid to the trade and development of weapons worldwide. The creation of advanced technologies, which if used would bring the whole of humanity and illegal trade to the brink, requires transparency from the producing States and a sense of responsibility to all world governments.

A Brief History of the Production of Weapons

The need to defend oneself from external dangers, whether they are generated by man himself or by nature, or the desire to extend his dominion to other territories, has always pushed the human being, gifted with an intellect superior to other living species present on Earth, to study more sophisticated methods of making weapons.

Over the centuries, during the creation of the first human appropriations, the new figure of the warrior began to develop. It grew from the era of the great Egyptian pharaohs, the Greeks, the Persians, and the Romans onward, a real modern army divided between draft troops and professional soldiers, trained in hand-to-hand combat and the use of weapons since from a young age. His job was to defend against enemy attacks and start military expansion campaigns to increase possessions.

At that time, the production of weapons was always the preserve of local craftsmen, specialized blacksmiths, who forged swords and shields

for the warriors and for the gentlemen who commissioned their invoice. The figures of the “Armourer” and the “Gunsmith” distinguished the production of defense weapons, or “white weapons,” such as armor and shields (in the first case), and of offense, such as swords and weapons by fire (in the second case).

The Persian Empire, the largest of the ancient empires, had very strong, multiethnic warriors, the most famous of them called “immortals.” The weapons that the soldiers used were advanced and valuable, like the famous swords: the “akinaka” and the “shamshir.” The Persian army was the first to concretely develop naval warfare.

The archaeological finds demonstrate how the Hellenic gunsmiths were skilled workers of metallic materials and managed to create weapons not only of the highest quality but also with artistic touches of great importance. Famous were the large bronze shields, the “oplons,” and the armor that covered the bust. The Greeks were formidable navigators and strengthened their naval war fleet to the extent that they were large like modern ones.

Alexander the Great, in 336 BC, innovated the Greek army, also taking inspiration from the Persian one. He created an army with various integrated departments, introduced crossbow and catapult, founded military academies, and adequately equipped his men to make them more agile but at the same time fearsome.

Despite the little news found about the production of weapons, during the Roman Empire the weapons were produced by three main producers. The first were the “*fabricae*,” as attested by the “*Notitia Dignitatum*,” a text (the official discussion of which is still much discussed) containing the list of Roman military and civilian positions in the late empire. The “*fabricae*” were managed by the “*magister officiorum*” which had control over the “*fabricenses*,” i.e., those who worked in the *fabricae*. With Diocletian, the “*Fabricae*” became a state factory. The second producer were the legions, which were provided with highly specialized personnel (*gladiarii*, *scutarii*, *sagittarii*) inside the camp, capable of repairing and producing weapons for the soldiers. The third producer remained the individual craftsman.

The production of private weapons was often still carried out in places where the production of state factories was far away.

During the Middle Ages, cavalry, prominent in the uses of barbarian peoples, took the place of infantry. In the Carolingian era, valuable armor also covered a considerable cost for their splendid invoices. But from the tenth century after Christ, the “chain mail” began to spread and the art failed in the manufacture of armor. In the fourteenth century, there was a new important change with the new “plate” armor. We saw the spread in the renaissance of important manufacturing centers for valuable armor. In the Holy Roman German Empire, the guilds of craftsmen who forged weapons flourished in its large cities.

In the transition from the ancient world to the Middle Ages, the development of society saw, therefore, an evolution of the art of war and weapons progressed becoming more sophisticated and deadly. What radically changed the world of weapons was gunpowder. This appeared in ninth-century China and then spread throughout the Asian and European continent. The first weapon was the siege mortar, which allowed to weaken and destroy the walls of the mighty castles.

With the passage to the nation-states in the fifteenth century and the decline of the feudal one, the army became permanent and professional. We pass shortly after the wars of conquest to the wars of attrition. It was during one of these wars, the Thirty Years’ War (1618–1648), that Gustavo Adolfo invented the paper cartridge for better functioning of the rudimentary rifle.

On an economic level, the passage from the great empires to the nation-states, often led by an absolute monarch, led to difficult maintenance of the expenses of military campaigns in a context where the appearance of financial instruments, banks, and traders gave way to an embryonic international economic system. Thus, often the sovereigns in conflict with each other could not stay there long if not at risk of getting into debt and subsequently having to declare bankruptcy.

All this continued until it reached the two industrial revolutions when, first in England, then in the rest of Europe, it went from artisanal

production to an industrial production that was aimed at the mass.

Great protagonists changed history by revolutionizing the weapons existing in those centuries of great innovations – among them: William George Armstrong, who invented the rifled cannon with a retro-charge; Joseph Whitworth in Great Britain, with the invention of the Whitworth rifle, used by the British army; Alfred Krupp in Germany with his steel factory in Essen; Adolphe and Eugene Schneider in France with their steel mill that produced cannons, tanks, ships, submarines, locomotives.

During the modern age, colonialism saw the European powers (Great Britain, France, Portugal, Spain, and the Netherlands) succeeding in predominating over the populations of the territories not yet “civilized,” thanks to their social and economic organization, but, above all, thanks to their power of arms compared to those of the local peoples.

The American War of Independence (1860–1865) was the first modern war to see both peoples fighting with each other involved and an industrial apparatus aimed at their maintenance and production of weapons. The trains allowed a rapid and consistent supply of troops even over long distances.

The second industrial revolution (1870) continued the innovation process, characterizing the new technologies not as the result of an almost random nature but of careful and financed research of specialists and universities.

It is in this period that repeated conflicts gave birth to the machine gun, the mine, the rifles, and the pistols (in addition to the cannons), which greatly improved accuracy and shooting distance. Warships enhanced the iron hull, incorporating turrets with multiple cannons until they reached the modern battleships. In the early 1900s, the submarine made its appearance and in 1903 Orville Wright with an internal propulsion engine flew a first embryonic airplane within seconds.

However, it was the two great wars that characterized a real arms race. Nations converted industries into war and weapon industries, thus radically transforming their economies. Weapons became an instrument of advanced and mass

death. Airplanes, tanks, ships, and submarines had become the tools of death that the whole international community was accustomed to knowing and to fear.

At the end of the Second World War, on August 6 and 9, 1945, the release by the USA of the first two atomic bombs on Hiroshima and Nagasaki, in Japan, certainly marks the culmination of the destructive power of the two wars and gave the whole international society the sense of insecurity to which it was necessary to remedy with closer control of governments and cooperation that increasingly focused on peace.

Thus was born in the same year the UN that gathered around the main nations of the world and had as its objectives the maintenance of peace on the whole planet and the progressive disarmament as well as an arms control and management.

The so-called Cold War (1962–1991) which accompanied the difficult post-war years continued under the banner of such insecurity. The USA and the USSR threatened to unleash a third world conflict that would certainly have been fought with the use of nuclear weapons and mass destruction. The sense of responsibility on both sides averted the worst for the entire international community. In this period, however, both sides were several times on the point of no return and both powers found themselves arming the Satellite States to secure military bases and allied countries already armed in case of world conflict.

The “Nuclear Age”

Nine States have nuclear weapons in the world and only the USA and Russia own 95% of the world’s arsenal (Granoff 2015). The other States are Great Britain, China, Pakistan, France, India, North Korea, and Israel. South Africa renounced nuclear weapons in 1991. The outbreak of a war that could trigger the use of nuclear bombs would jeopardize the existence of entire populations and would be catastrophic.

The “Nuclear Non-Proliferation Treaty – TNP,” signed on July 1, 1968, and entered into force on March 5, 1970, featured both nuclear weapon countries and countries that did not have

them. The international treaty, and its 11 articles, aimed at disarmament, nonproliferation of nuclear weapons, and their peaceful use. For this reason, on that occasion, it was established that the countries possessing nuclear weapons should not transfer atomic weapons unless under the control of the IAEA (International Atomic Energy Agency) and the countries without them should not try to get hold of them. Currently, 189 countries are signatories to this treaty.

Also, for this reason, the USA and the then USSR signed the first agreements called SALT "Strategic Armaments Limitations Talks" on May 26, 1972, and decided that the number of missiles produced and held ("ICBM" intercontinental missiles and "ABM" anti-missile missiles) should be limited. On that date, the anti-ballistic missile treaty "ABM Treaty" was also signed, which then entered into force on 3 October of the same year. SALT II signed on June 18, 1979 was the fulfillment of the agreements on the limitation of the production of strategic weapons. The "INF Treaty" for the elimination of intermediate and short-range missiles was signed on October 11, 1987. In the climate of the so-called Cold War, agreements continued slowly and with continuous suspension. Thus on July 31, 1991, the agreements on the reduction of weapons owned by the two superpowers continued with the signing of the "START – Strategic Arms Reduction Treaty" agreement, later called "START I" after the signature of January 3, 1993, of the agreement called "START II."

On May 24, 2002, in Moscow, the two superpowers signed the "SORT – Strategic Offensive Reductions Treaty" agreement also known as the "Moscow Treaty," which had among its objectives the common reduction of nuclear warheads by the end of 2012. On April 8, 2010, USA and Russia signed the "New START" agreement which replaced all the previous "START I," "START II," and also the "SORT." The "New START" aims to reduce the limit of nuclear warheads provided for by the "SORT" by 30% and lasts for 10 years, which can be extended to 15, unless a new agreement is signed between the parties.

The UN and the Arms Treaties

The United Nations has among its objectives the creation of peace between the nations of the world and disarmament and control over weapons. Over time, these objectives have given rise to some of the following tools and treaties.

The "Convention on Certain Conventional Weapons – CCW Convention" (signed on October 10, 1980, in Geneva and entered into force on December 2, 1983) aims to prohibit the use of weapons that are particularly dangerous or that would indiscriminately affect even the civilian population. This Convention is made up of five protocols in which they desire to protect human life as much as possible is evident by prohibiting the use of weapons that produce fragments, mines, and traps, incendiary weapons, blinding lasers, explosive remnants of war. To date, 125 are the signatory States of the Convention (plus 4 signatories).

The "UN Register of Conventional Arms – UNROCA" (created in 1991) is the register containing reports on the legal arms trade declared by 170 states in order to create trust and transparency and discourage massive exchange between countries by also activating diplomacy systems preventive.

The "Convention on the Prohibition of the Use, Stockpiling, Production and Transfer of Anti-Personnel Mines and on their Destruction – Ottawa Treaty" (signed on December 3, 1997 and entered into force on March 1, 1999) has been ratified by 164 States with, however, the absence of states such as China, Pakistan, Russia, USA, India, and South Korea. The objectives of the Convention were the rapid destruction of the stocks of anti-personnel mines owned by each state, the reclamation of the mined areas within 10 years of entry in force of the Convention and assistance to victims.

The "Program of Action to Prevent, Combat and Eradicate the Illicit Trade in Small Arms and Light Weapons in All Its Aspects" (adopted in 2001) was created to contrast the illicit market for small arms and light weapons. Two subsequent review conferences in 2006 and 2012, four

biennial meetings, and a meeting of experts from the various governments in 2011. In 2005, the “International Tracing Instrument (ITI)” was introduced asking the states that they adequately mark the weapons and that they create and maintain the relevant registers also to create greater international cooperation aimed at tracking. Achieving this goal is part of the 2030 Agenda for Sustainable Development.

The “Firearms protocol” (resolution 55/255 of May 31, 2001, signed on July 11, 2001, which entered into force on July 3, 2005) is the protocol against the illicit manufacture of weapons which completes the “United Nations Convention against Transnational Organized Crime (Organized Crime Convention).” The protocol sheds light on the need to manage arms trade flows to prevent them from being intercepted by the illicit market.

The “National Legislation on Transfer of Arms, Military Equipment and Dual-Use Goods and Technology” (adopted in 2003) deals with regulating the trade in weapons, software, and technologies potentially usable in two versions both by the military and by the civilian population. This regulation requires a great deal of research about new technologies and the exchange of information between states, an effort required by the UN General Assembly.

The “ATT-Arms Trade Treaty” (adopted on April 2, 2013, and entered into force on December 24, 2014) is the first international treaty aimed at two main objectives: the regulation of the arms trade and the fight against illicit trafficking. The treaty aims to raise contracting states’ awareness of the suffering caused by weapons in the hope that the path of disarmament will soon be followed. There are 96 States Parties and 130 are the signatories. Articles 6 and 7 are important. Article 6 lists the cases where the arms trade is prohibited; Article 7 instead lists the criteria according to which a state must accept or reject an export request. The fourth conference of signatory states was held in Tokyo in August 2018 in which efforts were made to reach more and more low-income states, especially in the Middle East and North Africa.

SIPRI and Data on the Arms Trade

The independent international institute SIPRI, “Stockholm International Peace Research Institute,” was founded in 1966, to study and analyze conflicts, military expenses, armaments, and arms trade, with a view to “peace study.” Since 2011, in its “Yearbooks,” SIPRI has published the annual data obtained from its research translated into different languages.

SIPRI estimates that global military spending totaled \$ 1.822 billion in 2018. This expenditure was 2.6% higher than in 2017 and 5.4% higher than in 2009. The USA in a logic of increasing the stock of weapons (conventional and nuclear) in their possession and an increase in military salaries have military spending increased by \$ 649 billion.

In the 2019 Yearbook, SIPRI classifies the top five exporting countries: the USA, Russia, France, Germany, and China; and the top five importing countries: Saudi Arabia, India, Egypt, Australia, and Algeria.

To date, SIPRI tells us about an international reality in which the transparency of the data that each State delivers to the UN, regarding the production and trade of weapons, is increasingly fundamental. International arms transfers increased by 7.8% between 2009–2013 and 2014–2018. Seventy-five percent of the market is occupied by the five major world producers. The gap between the USA and Russia (first and second world producers respectively) was 12% in the period 2009–2013, reaching 75% in the period 2014–2018.

The volume of these exports sees Asia, Oceania, and the Middle East among the main importing countries. Asia and Oceania collect 40% of imports in the period 2014–2018 and the Middle East 35% with an increase in flow in the periods taken as a reference. In the 2014–2018 period, Europe imported only 11% and Africa imported 7.8%.

The SIPRI in its Yearbook studies and analyzes data relating to the major arms industries. According to SIPRI, the top 100 producers generated \$ 398 billion in 2017.

Still in the global framework outlined by SIPRI, there are 36 multilateral arms embargoes imposed in 2018 – 14 UN, 21 EU (of which 10 implement UN ones), 1 Arab League. These embargoes were aimed at IRAN and North Korea while some EU also addressed Russia and Syria.

The four control systems envisaged for continuous technological updating and to combat illegal purchases are still active:

- Australia Group (AG)
- Missile Technology Control Regime (MTCR)
- Nuclear Suppliers Group (NSG)
- Wassenaar Arrangement (WA)

The EU has sought to expand its interest in “dual-use” and the ongoing control of arms exports. The EU and the USA have tightened controls on foreign direct investment for these types of sensitive technologies.

Particular cases have been in recent years IRAN and North Korea. The “JCPOA - Joint Comprehensive Plan of Action” is the agreement signed on July 14, 2015, in Vienna for the elimination of medium-enriched uranium and the 98% reduction of low-enriched uranium in Iran to end heavy sanctions economic measures of resolution 1747 for the nuclear program setup. Furthermore, on the principle of nonproliferation, Iran has undertaken not to build new heavy water reactors. In 2018, however, a crisis scenario opens with the USA which, by requesting the Government to withdraw the Pasdaran from Syria, unilaterally abandons the agreement and once again requires economic sanctions on Iranian oil and banks. The European Union criticizes the US choice, which sees in this choice the risk of weakening the moderates present in the country in favor of ultraconservatives. Tensions rise after the Iranian ultimatum in 2019 and the killing of General Qasem Soleimani in a US raid in 2020, and Iran announces that it will resume the nuclear energy program.

North Korea has resumed its nuclear program since 2006. According to the SIPRI calculation in January 2019, the Asian country would have owned about 20–30 nuclear warheads. The

escalation with the USA, which also threatened armed intervention if necessary, stems from the latter’s request to suspend nuclear tests started by the North Korean regime. The UN Security Council has also imposed economic sanctions, including restrictions on oil imports for the Pyongyang government. The ongoing negotiations will hopefully ward off conflicts that could lead to the use of atomic weapons.

Cybersecurity, Darknet, Terrorism, and Submerged Markets

The Europol “European Police Office” was born on July 1, 1991 to combat criminal activities carried out within the European Union. Illegal (including computerized) arms trade is still widespread in the less politically stable areas of the planet, but not only. Being the payment of weapons in the so-called Darknet (black market of the network) completely anonymous, it allows the buyer not to be traced and in some cases to buy with cryptocurrencies. The Darknet is in itself a flexible tool, in a continuous state of innovation and above all without any border barrier. Also for this reason, collaboration with the private sector through public–private partnerships is fundamental in combating these types of crime.

With the Schengen Treaty and the elimination of borders between European states, it requires further internal control over the flow of firearms. The European Directive 91/447/EEC created the “European Firearms Card” which is issued to anyone who holds firearms. After the signing of the “United Nations Protocol against the Illicit Manufacturing and Trafficking of Firearms,” additional to the “United Nations Convention against Crime,” this directive was updated. Directive (EU) 2017/853 and Implementing Regulation 2015/2403, following the terrorist acts in France, were instead evidence of a greater awareness of the need to combat the terrorist use of firearms (Nunzi 2018). The European Agenda on Security was equally relevant.

The European Security Agenda (of April 28, 2015), providing for shared actions between the European Union and the Member States, has been

prepared for the maintenance of security within European borders and the effective contrast of terrorism, organized crime, and computer technology.

Illegal weapons mainly come from smuggling routes that see the Balkans as protagonists (where the arms embargo on the former Yugoslavia favored illicit trafficking often in the hands of local mafias), North Africa (especially the Maghreb, Tunisia, Morocco, Algeria), and the Middle Orient.

The small arms and light weapons, “SALW,” of which the western countries are exporters, are the most smuggled and also those which are held responsible for the greatest number of deaths each year.

Key Issues

In addition to being a trade with decidedly important revenues, the arms trade is closely linked to the confluences that still today do not cease to inflame entire areas of our planet. Furthermore, illicit trade feeds terrorist and criminal groups that do not help stabilize these areas. The lack of transparency of the States toward the UN on the arms trade still allows getting lost in the flow of weapons destined for submerged markets.

Future Directions

In the near future, it will be necessary to implement transparency between States through the implementation of UN brokerage and to promote cooperation, disarmament, and peace more and more. Countering the illegal trade in weapons must always be a priority for all producing states that must increasingly control the flow of weapons they produce with greater accuracy. New technologies will increasingly focus on sophisticated and deadly systems of armaments which, if not regulated and ended up in the Darknet, in the terrorist and criminal circuit, could prove potentially harmful to all humanity. The steps on Cybersecurity are still not well defined and soon need clear lines of intervention shared globally.

Even the steps of the “Biological and Toxic Weapon Convention - BTWC” on the disarmament and nonproliferation of chemical and bacteriological weapons are, despite the growing attention, still not entirely sufficient in a world scenario in constant evolution.

Summary

The arms trade found its beginning in ancient times, with ancient civilizations often fighting for territorial supremacy and the appropriation of resources. The weapons have thus been increasingly advanced and deadly over the centuries. The watersheds between ancient war weapons and modern war weapons were the two great industrial revolutions and the two world wars. The arms race of those years was a run-up not only to greater productivity but also to the search for the most sophisticated offensive and defensive technology. Thus arrived at the end of the Second World War the weapon that would have frightened the entire planet for its destructive force: the atomic bomb. Today the arms trade follows several paths, legal and otherwise. Darknet today is one of the most important threats that prevent a real fight against arms smuggling, and for this reason, the global role of cybersecurity becomes increasingly important. The SIPRI, Stockholm International Peace Research Institute, founded in 1966, analyzes world trade in its “Yearbook” and gives the world governments the picture of the major exporting countries and the major arms importing countries of the world.

[Nonflammable](#)

Definition

The term asbestos is a trade name given to minerals or a range of fibrous silicates that occur in polyfilamentous bundles. These naturally occurring, extremely flexible fibers are characterized by thin fibrils and are easily parted from each other (USGS 2001; Health and Safety Executive 2005).

The six different minerals that are known as asbestos are crocidolite (blue asbestos), chrysotile (white asbestos), amosite (brown asbestos), anthophyllite (gray or dull green), tremolite, and actinolite asbestos. These belong to the serpentine (curly shaped fibers) or amphibole (needle shaped fibers) families (Bartrip 2004).

Brief History

Asbestos has a very important characteristic, namely, it can withstand very high temperatures. Given this property, asbestos quickly became indispensable in the construction and shipbuilding industry. What made it even more attractive was that it was cheap and durable and therefore very profitable. Companies jumped in on the chance to be able to cash in on the insatiable demand for the product throughout history across the world. At its peak, there were over 3000 products that contained asbestos (Bartrip 2004).

Issues with Asbestos

The inherent indestructibility combined with its fibrous nature made asbestos deadly. The fine fibrous particles loosened routinely in the air, in the process of mining, manufacturing, constructing, or any process that created dust, could be inhaled into the lungs. It is now known that prolonged exposure to such asbestos dust causes a form of lung and abdomen lining cancer called mesothelioma. It is also known to cause asbestosis which is a severe lung infection that makes breathing eventually impossible.

Asbestos is classified as a Group-1 carcinogen, which means the material can cause cancer in humans. To put this into context, for example, glyphosate and DDT have a Group 2A classification which is reserved for materials that “probably” cause cancer in humans (IARC 1977, 1987).

In the years between 2007 and 2017, the deaths and disability-adjusted life years directly related to asbestos increased by 19.6% and 15.3%, respectively (Murray 2018). According to ILO, about 100,000 people, every year, die due to asbestos exposure at their place of work with experts stating that even many more people die outside their place of work due to the same reason (“Asbestos still pushed,” 2014).

Responses to Asbestos

Despite the serious health dangers posed by asbestos, mining for it continued.

In the earlier period, while most of the fabrication work was being done in the USA and the UK, mines were operating in Canada, South Africa, Russia, and Zimbabwe.

For a large part of the twentieth century, Canada’s Quebec province, with its several dozen mines, was the world’s chief asbestos manufacturer and exporter. When a new local government questioned why the province was still producing and exporting something that its own citizens had already rejected, Quebec Province eventually ceased its asbestos business in 2012 (“Asbestos still pushed,” 2014). The last Canadian mine finally closed down in 2011, but it was only in 2018 that a complete country-wide ban on asbestos was put in place (Mauney 2019).

Throughout the EU, asbestos was finally banned in 2005. As of July 2019, around the world, 67 countries have banned the use of all types of asbestos (Ibase Secretariat n.d.).

In the USA, however, there is still not ban despite the obvious health warnings and EPA activism. Despite regulating its use and reduction

in consumption, the USA continues to be a relatively large importer and consumer of asbestos (King 2019).

Liability Consequences

Asbestosis may take up to 30 years to develop, and mesothelioma can be dormant for up to four decades. In other words, workers are likely to carry on working in their respective careers not knowing that they are getting seriously ill. WHO estimates that around the world, about 125 million people come into contact with asbestos in their workplace environment every year (“Asbestos still pushed,” 2014).

The liabilities that arise in companies therefore accumulate over decades (Maiden 2010). Presently, around the globe, there are numerous asbestos-related court cases going on. These are primarily trying to hold (the accused) companies responsible for not safeguarding the health of their immediate stakeholders such as employees and community.

Given the obvious, the insurance industry has been reducing coverage for asbestos exposure-related issues since the early 1900s. Over 730,000 asbestos-related claims, costing the insurance industry about US\$ 70 billion, have been made in the USA since 1970 until 2002 (Selby 2019). Many such litigations, in the USA alone, have led to business insolvencies, which in turn have resulted in over 60,000 job losses (ISSA n.d.). Between US\$ 200 and 300 billion is what the insurance industry expects to be the all-inclusive future cost of asbestos-related cases (Selby 2019).

Current Outlook

Despite the well-documented health hazards, the commercial production and use of the toxic product continues, especially in the developing world. Most of the production and recycling of the hazardous material has now moved to

developing countries where the safety standards are relatively relaxed. Here, the regulatory governance tends to be weak, and workers are often uneducated or relatively uninformed. They are sometimes simply unaware of the hazardous situation they are putting themselves into and sometimes given their poor economic backgrounds, they are unwilling or incapable of fighting for their rights. Heavy asbestos-based industries, such as those that dismantle ships at the end of their useful lives (ship graveyards), or industries which dispose-off boilers by breaking them up, or even industries that recycle automotive parts, thrive in low- and middle-income countries like India.

U.S. Geological Survey (USGS 2017) states that the BRIC countries (excluding India) were leaders in terms of asbestos mining in the years 2015 and 2016. Of these, in 2017, only Brazil finally banned the use of asbestos and shut down the business itself in the country (USGS 2017).

Some countries like India have also very recently stopped mining for asbestos, mostly for quality reasons, in that the asbestos mined here is of low quality. However, up until 2015, 17 asbestos mines were still active in India. Asbestos imports have also become cheaper mostly pushed by Canada (Jadhav and Gawde 2019). India and China are among the largest consumers of asbestos in the world with others being Indonesia and Russia (Frank and Joshi 2014).

Jadhav and Gawde (2019) state that the deaths related to cancers caused by asbestos exposure are increasing around the world with India being at the forefront given its conducive affinity towards the asbestos processing industry. According to them, in the coming years, half of the expected 12.5 million global asbestos-associated illness patients, will be in India. They also however clarify that the actual facts and figures may be skewed (downwards) given the limited capacities within the Indian health system (Jadhav and Gawde 2019).

Despite this, India continues to promote the products containing asbestos for economic reasons.

Possible Solutions

In parts of the world such as in the USA, consumption of asbestos minerals has gone considerably down from over 800 thousand tons in 1973 to about 300 tons in 2017 (Flanagan 2018). Several alternatives such as different materials, substitutes, and even new technology have been and are also currently being explored. Some of such alternatives have already led to replacing asbestos thereby resulting in its decline.

According to Flanagan (2018), this decline in the use of asbestos will continue with non-asbestos substitutes becoming more and more mainstream. Castleman (2009) provides a long list of possible substitutes for different purposes along with their suppliers in different parts of the world. Some of these are amorphous silica fabric, cellulose fiber, polyurethane foam, flour fillers, and thermoset plastic flour.

Asbestos is and will continue to be a cheap and economically lucrative option to many of the growth and development problems of countries and their citizens. Moreover, given the rather long cancer development latency resulting from exposure to the toxic product, many corporations find it relatively easy to shrug off their responsibilities, a problem exacerbated by the short-term focus on shareholder wealth maximization.

According to “Asbestos still pushed” (2014) article, toxicologists financed at least partly by the asbestos friendly industry, downplay the carcinogenic impact of the toxic product and claim that the WHO is scaremongering. In a poor country like India, affordable housing is beyond reach for millions and this is where asbestos-based roofing sheets come into play. Big multinational organizations lobby governments of poor countries and push toxic asbestos products consciously burying valid concerns (“Asbestos still pushed” 2014).

Unless a worldwide ban is imposed on the product and its use, this seems to be just another ticking bomb driven by corporate greed for higher profits and complete disregard to stakeholder welfare.

Department of Business Administration, New Bulgarian University, Sofia, Bulgaria

Synonyms

Ashoka innovators for public

Definition

“Ashoka (Innovators for the Public)” was created on June 3, 1980, by Bill Drayton. Ashoka (IFP) is registered with a \$ 50,000 start-up capital, as an international non-profit organization in District of Columbia, USA. The headquarters of the company are located in Arlington, Virginia, USA, Tax ID #: 51-0255908 (Annual Reports 2019).

Ashoka (IFP) is the world's first professional organization for “social entrepreneurship.” Its founder and author of the term “*social entrepreneurship*,” Bill Drayton, gave the organization the name “Ashoka,” named after the Indian ruler, Ashoka Maurya, focused his policy on the poor, ensuring the welfare of his people and the maintenance of basic human values (Bhatta 2000).

What is “Ashoka (Innovators for the Public)?” The answer of the organization itself is: “Ashoka is a network addressing the world's most pressing problems. We identify and accelerate cutting edge social innovation: whether in social

entrepreneurship, education or business. By bringing together these communities across sectors we are building a world in which everyone is equipped and empowered to be a changemaker” (What is Ashoka? 2017).

Ashoka does not accept funding from government entities. Its activity is provided by individual and institutional endowment funds (Charity Navigator – Your Guide To Intelligent Giving” n.d.-a).

Introduction

There is a distinction between traditional entrepreneurship and social entrepreneurship. While traditional entrepreneurship uses neutral mechanisms and creates goods that are appropriated on a market principle and become private goods, social entrepreneurship creates “public goods.” While traditional entrepreneurship creates products, looking for market niches, social entrepreneurship is looking for “social niches” for which it develops its products and services. When designing their products and services, they are concerned whether people have access to them and how many people have access to them. For social entrepreneurship, the leading incentive to start an entrepreneurial venture is to create products and services that more people need and who cannot afford them in the existing market pattern of distribution. (This also embodies the principle of “scalability” of social entrepreneurial projects.) Social enterprises usually direct their efforts to the so-called “market failures” (Chahine 2016, p. 3).

In our opinion, Social Entrepreneurship is emerging and evolving due to the rising income inequalities in the world, which peaked in the mid-1970s and 1980s of the twentieth century. It is still high and will remain high as predicted for a long time (Roser 2019; Lakner and Milanovic 2013).

Key Issues

What is “Social entrepreneurship and social entrepreneur” in Ashoka’s vision?

There are many definitions of the phenomenon “social entrepreneurship” (Mair et al. 2006). “Social entrepreneurs are the essential corrective force. They are system-changing entrepreneurs. And they are committed to the welfare of all” (Drayton 2019), and “Social entrepreneurs are individuals with innovative solutions to society’s most pressing social, cultural, and environmental challenges. They are ambitious and persistent – tackling major issues and offering new ideas for system-level change” (Social Entrepreneurship 2019).

According to Ashoka what is a social entrepreneur? The answer is given by one of the leading fellows of Ashoka: “So what is a social entrepreneur really? A social entrepreneur creates innovative reinforcement systems that serve people or causes lacking resources, thus generating surplus value that the entrepreneur reinvests to grow and improve those systems. Or something like that” (Castro 2016).

Here are three key phrases: “corrective force,” “social innovations,” “producing surplus value.” Social entrepreneurship is a force that corrects the failure of market allocation. At the same time it is an innovative force that creates value added.

The company’s goal is to create professional social entrepreneurs (Ashoka: Innovators for the Public – NGOs India 2018).

“*Organization of the civil sector*”: Ashoka (IFP) prefers to be termed the “organization of the civil sector” to emphasize what it is and not what it is not.

Structure and Activities

Ashoka (IFP) at present includes more than 3500 leading social entrepreneurs in over 92 countries (Ashoka n.d.-a)

The organization includes the following programs for the development of social entrepreneurship:

1. *Ashoka Fellows*. These are specially selected. They receive a 3-year scholarship with which they are not allowed to fund their entrepreneurial initiative. The scholarship is granted to

cover costs for the development of their entrepreneurial idea. They receive support from specialists in the given area of the Ashoka global community (Ashoka 2017a).

2. *Ashoka Venture and Fellowship*
3. *Ashoka Support Network (ASN)*
4. *Executive in Residence (EIR)*
5. *Ashoka Changemakers*
6. *Ashoka Youth Venture*[®] (Ashoka n.d.-b)

Ashoka's main activities are Fellows and Venture Social Capital.

Ashoka Fellows are specially selected. Leading criteria are creativity and social scalability of the project, readiness to work for the public, and not for personal benefit. They receive a 3-years scholarship, which is determined individually for each of the fellows. The scholarship is not granted for financing the entrepreneurial initiative. It is granted to cover the fellows' personal expenses for the development of their entrepreneurial idea. They receive support from professionals and successful social entrepreneurs in the given area of the Ashoka global community (Ashoka 2017b).

Social Venture Capital

"Ashoka" finances Fellowships by raising funds from donors. These funds are used as venture capital. The organization is a pioneer in creating "*social venture capital*." Social venture capital differs from traditional venture capital in that social investors do not have as their primary objective the monetary return from the investment. Social venture investors are *ethical investors*. They invest in businesses that would make the world better with their goods and services and have the potential for development. They usually invest in social niches, which are not occupied by traditional investors and public organizations, with the potential for scaling.

Social venture investment differs from traditional venture investment in the way they assess the potential of entrepreneurial endeavors. First of all, these new businesses must meet certain ethical and social standards.

The Social Venture Investor is active in managing the company. The social venture investment is longer than the traditional one, which is usually for less than a year, while the social venture funding is for a minimum of 5 years. While traditional venture investment is project financing, the social venture funding is financing the entire entrepreneurial venture. It does not focus on tangible assets but on intangible assets and mainly on intellectual and human capital (Roger 2007).

Ashoka applies the so-called "five why's" technique in its Guide to Social Venture Investor Guidelines. They are related to addressing local and global social and environmental issues. Only when the owner of the venture capital answers these questions, may he ask himself how can I intervene, how can I increase my investment in solving this public problem? (Ashoka n.d.-b).

Ashoka Changemakers

In 1993 Ashoka began publishing the first professional magazine "Ashoka Changemakers." Changemakers "activates a global network of social entrepreneurs, innovators, business leaders, policy makers and activists to build everyone a Changemaker world" (Ashoka n.d.-c).

Ashoka Changemakers[®] is a program of the foundation that in a three-step process – frame, convene, and ignite, works with the other Ashoka structures in a global network and partners to frame an approach to a problem that exponentially accelerates social change (Ashoka n.d.-d).

Financial Conditions

The financial position of Ashoka was rated with 81 points (max. 100) by Charity Navigator (the largest rating agency for charities). The organization maintains good financial health, but its activity is apparently limited after 2014 (Fig. 1).

Ashoka (Innovators for the Public), Fig. 1 Ashoka, Balance Sheets, 2017–2005. (Data Source: Charity Navigator – Your Guide To Intelligent Giving, Ashoka Historical Data [n.d.-b](#))

Conclusions

Ashoka creates a new model of entrepreneurship-social entrepreneurship. It is based on the discovery of “market failures” and the lack of adequate governmental intervention to correct them. Ashoka changes the vision for entrepreneurial purposes; the goal of the entrepreneur is not to create only monetary profit but to create value added for society and produce public goods accessible to those who, under the existing system of distribution of income and wealth, were earlier inaccessible.

[Assurance of sustainability reports market](#)

Description

The assurance market for sustainability reports arises from the need to increase the credibility of information on corporate social responsibility (CSR). The essence of external assurance is that the information is more credible if it has been examined by an expert who is unrelated to the reporting party. Its objective is to reinforce the users' confidence in certain information, through analysis by an independent third party that establishes an opinion about its adequacy and veracity.

Sustainability reports and traditional financial reporting are an important source of information to support the decision-making process within the

new context of business responsibilities understood from an economic, social, and environmental perspective. This circumstance favors the creation of a market for external assurance services and provides an opportunity for different professionals facing an emerging demand.

As in any external assurance service, three participants can be distinguished a priori in this market: companies that hire the service, professionals who implement it, and users of the information. This market is widely considered as the expansion of the financial audit market. However, the particular characteristics of sustainability information and the absence of legislation in this area cause differences between both two. In this sense, the voluntary nature of the demand, the wide number of professionals competing in the market, and the use by an extensive range of stakeholders, beyond shareholders and investors are all worth highlighting.

Introduction

The creation of a market arises from the existence of a need that encourages the demand and the supply of a certain good or service. The need that justifies the external assurance of sustainability reports derives from the evolution of the way the role of companies in society is understood. Social responsibility is established in the twenty-first century as a fundamental principle of the sustainable performance of companies, i.e., way in which organizations are able to respond to the interests and expectations of their stakeholders (AccountAbility 2008a). The value of a company ceases to be only measured from an economic perspective, and it now includes social and environmental impacts. This entails the expansion of the transparency concept in terms of information content and receivers (see ► [“Communication of CSR Information”](#)). Thus, financial information is insufficient for decision-making by a broad group of stakeholders. Nonfinancial information is important even for more traditional groups, namely, shareholders and investors (Berthelot et al. 2012; Cheng et al. 2014; Orlitzky et al.

2003; Schadewitz and Niskala 2010). Given this paradigm, the external assurance of CSR disclosures has become a fundamental component for increasing the stakeholders' confidence in information (Darus et al. 2014; Herda et al. 2014). This service is required to equate CSR information to financial information in decision-making processes (KPMG 2011).

In the case of financial audit services, three fundamental pillars justify the existence of their market: the responsibility relationships of companies, the need to generate credible information, and the usefulness of such information for decision making (Flint 1988; Lee 1993). This justification is attributable to any external assurance service (Fig. 1) in which, at least, three actors with different roles and responsibilities are distinguished: the party that hires the service, the professionals who perform it, and the information users (IAASB 2013). Companies hiring the service to an external professional are ultimately responsible for the information issued to their stakeholders. Professionals are the assurance service providers responsible for obtaining sufficient and adequate evidence to issue an opinion that improves information credibility to users (see ► [“Standards for the Assurance of CSR Information”](#)). Users are those individuals and organizations that use the information to facilitate their decision-making process. Therefore, disclosure of credible sustainability reports is based on the interaction between companies, assurance suppliers, and stakeholders (Park and Brorson 2005).

Despite this common justification, the differences between financial and nonfinancial (sustainability) information lead to differences in the way their respective assurance markets work.

A fourth actor participates in the specific case of the mature financial audit services market: the State, acting as regulator (Fig. 2). Its role is to achieve an adequate market balance, both in terms of quantity and quality, to guarantee user rights on the information issued by companies (Angulo 1995). Thus, legislation establishes the obligation to demand the service from certain companies, regulates the professionals who offer it, and arranges the attributes the service must possess

Assurance Market,
Fig. 2 Participants in the financial audit market

to meet the expectations of users, mainly investors and shareholders, under the premise of public interest.

Unlike financial auditing, external assurance of sustainability reports and its respective market are still in their early stages of development. This situation is partly attributed to the absence of legal requirements for assurance processes for CSR information (Ackers and van Heerden 2015; Darus et al. 2014). This circumstance affects the establishment of offer and demand, configured under the premise of willfulness. Likewise, it is important to note that the wide range of users makes it difficult to determine their expectations and needs.

In the absence of the fourth element identified in the audit market (the State), the configuration of

the three common elements – demand, offer, and users – is analyzed below.

It should be noted that this chapter focuses on the assurance market of sustainability reports given the widespread use of these documents to communicate CSR issues (see ► [“Communication of CSR Information”](#)). The same conditions could be made extensive to other ways of communicating CSR, such as integrated reports or nonfinancial statements.

The Demand of External Assurance of Sustainability Reports

In the financial auditing field, regulation and State mediation encourage the market and avoid

underproduction of demand (Wallace 1980). However, in the case of the external assurance of sustainability reports, the absence of regulation implies a lack of a legal provision that forces companies to hire this service. This is voluntary yet highly recommended by some public and private agencies promoting CSR and standardization of sustainability information, such as the Global Reporting Initiative (GRI).

Despite this, the demand for external assurance has increased since the end of the twentieth century. The average growth rate of formal assurance of nonfinancial reports was around 20% between 1997 and 2007 (CorporateRegister.com 2008). More recently, the number of assured sustainability reports continues to grow in absolute terms (CorporateRegister.com 2013). This trend is reflected in the surveys about CSR reporting issued by KPMG (2002, 2008, 2013, 2017) that are used by numerous authors to demonstrate the importance this service has acquired (Deegan et al. 2006; Manurung and Basuki 2010; O'Dwyer et al. 2011; Pflugrath et al. 2011). The latest KPMG document shows how the demand for assurance continues rising internationally among large companies. In 2017, 67% of the G250 companies (world's 250 largest companies by revenue) and 45% of the N100 (top 100 companies in 49 countries) had their CSR reports assured, against 63% and 42%, respectively, in 2015 (KPMG 2017).

The existence of an increasing demand within the context of voluntary assurance allows to suppose the presence of a series of benefits and pressures that drive companies to hire them, despite their not being legally required to do so, thus allowing to justify the resources investment (CorporateRegister.com 2008; O'Dwyer et al. 2011). In addition to improving the credibility of information and its value for stakeholders, the assurance allows the enhancement of some aspects such as performance or corporate reputation (KPMG 2008; Marx and van Dyk 2011).

Numerous studies deal with setting some general patterns in the demand for assurance of sustainability reports by defining those

characteristics of companies dominating their configuration. In the same way that size and industry are widely considered in the literature as determining factors in the decision to publish CSR reports (Fifka 2013), these characteristics are considered determinants in the demand for external assurance. Thus, larger companies and organizations belonging to industries characterized by a lower confidence degree to their stakeholders, a greater social and environmental sensitivity and a high visibility for society, are more prone to externally assure their sustainability information (Castelo Branco et al. 2014; Fernandez-Feijoo et al. 2012, 2015; Marx and van Dyk 2011; Moroney et al. 2012; Sierra-García et al. 2013, 2014; Simnett et al. 2009).

The explanation for the voluntary demand of external assurance can be supported by the legitimacy theory (Lindblom 1994): companies exposed to greater public scrutiny and, therefore, with a greater need for being accepted (legitimized) by society are more likely to demand external assurance of their sustainability reports on a voluntary basis (Vaz-Ogando et al. 2018).

The Offer of External Assurance of Sustainability Reports

No regulation defines a specific profession to implement the assurance service of sustainability reports. Therefore, no profession has sufficient capacity to control aspects related to the exercise of the activity and the requirements demanded of those offering it.

In the decade of the 90s, authors like Elliot (1997) predicted the evolution of the audit profession to other market segments, considering the expansion of techniques, customers, and services needed to ensure its survival in view of the importance acquired by nonfinancial information (Wallage 2000). This expansion phenomenon includes the offer of external assurance for sustainability reports (O'Dwyer 2011). Given the similarities between financial auditing and the assurance of nonfinancial information, auditors

have great opportunities to provide this service (Ballou et al. 2006). However, the assurance of sustainability reports occurs in a competitive market where the accounting profession does not always dominate (Ballou et al. 2006; Pflugrath et al. 2011).

The existence of numerous professionals that compete in the assurance market encourages the debate about the characteristics of each type of provider, the way in which they offer the service or the most appropriate profile. However, there is no consensus on who should perform these services, what their competencies should be, or how the engagement should be accomplished (Deegan et al. 2006).

The literature mainly distinguishes between two groups of main suppliers, auditors, and consultants, considering that each of these two professions has a different approach when perform the assurance task (Manurung and Basuki 2010). The differences in the background of the diverse professionals potentially contribute to the variability in the assurance of sustainability reports processes as well as its results. In general, auditors are characterized by greater risk aversion, being reluctant to provide high levels of assurance and focusing more on consistency of information, accuracy of data, and the evaluation of control systems (Deegan et al. 2006; Manurung and Basuki 2010; Owen and O'Dwyer 2004). Likewise, they use a more conservative approach, influenced by the use of mandatory standards for their profession, ethical requirements, and control and quality mechanisms (Pflugrath et al. 2011; Simnett et al. 2009). However, the characteristics of CSR information, due to its predominantly qualitative nature, lead to the need for other evaluation methods beyond the rigor that defines financial auditing (Ballou et al. 2006). Thus, some authors believe that the accounting profession may lack certain necessary skills to face the difficulties presented by aspects such as the environmental impact assessment or the true level of commitment with stakeholders (Gray 2000; Manetti and Becatti 2009).

In contrast, consultants are characterized as having a more strategic approach focusing on the stakeholders' interests (Manurung and Basuki 2010; Owen and O'Dwyer 2004). Their main competitive advantage is their greater experience and knowledge in the social and environmental dimensions of CSR (Perego 2009; Simnett et al. 2010). Their procedures are more aimed at evaluating the communication process, considering measures of added value and sustainable performance under the premises of completeness, equity, and balance (Manurung and Basuki 2010; Owen and O'Dwyer 2004). Therefore, they are more likely to make opinions and improvement recommendations for reporting companies (Owen and O'Dwyer 2004; Perego 2009).

Despite the different professional approaches traditionally detected in the literature, the establishment of multidisciplinary teams and outsourcing are ideas gaining strength among academics (Adams and Evans 2004; Gonella and Woo 2000; Lewellyn 2000; Simnett et al. 2009; Wallage 2000) and standardization bodies (AccountAbility 2008b; IAASB 2013). This helps achieve the right balance of skills and competencies needed to add credibility to the process. This idea is reinforced in practice by the Big4 (Deloitte, EY, KPMG, PWC), large professional service firms that offer both auditing and consulting services, and the providers that have maintained the largest international market shares since the beginning of the twenty-first century (KPMG 2008, 2015; O'Dwyer and Owen 2005).

The Users of External Assurance of Sustainability Reports

Although the demand of assurance services is directly dependent on companies, it could not be maintained if no indirect demand by information final users was present (O'Dwyer et al. 2011). In the case of financial information, this and its consequent audit is traditionally intended for groups that need this information to control the

management of companies and/or make investment or financing decisions. The interests and needs of users, mainly shareholders and investors, are protected by existing legislation.

However, a wide variety of stakeholders with different expectations is contemplated regarding CSR disclosures (AccountAbility 2008a; Simnett et al. 2009; Spence 2009), as employees, shareholders, investors, consumers, suppliers, or local communities (CorporateRegister.com 2013). Likewise, although regulatory initiatives are beginning to become apparent in the field of non-financial information (as in the case of Directive 2014/95/EU), its particular characteristics make it difficult for regulatory bodies to verify and control sustainability reports with the same rigor as financial reports (Olson 2010). The defense of the interests and needs of multiple users would be the main motivation to promote the existence of legal requirements (O'Regan 2010). Nevertheless, it can also pose one of the main limitations for its existence, given the difficulty to identify specific interests (Dellaportas and Davenport 2008).

The absence of regulation and the existence of multifarious agents with diverse interests can lead to the emergence of an expectations gap that surrounds sustainability information (Manetti and Becatti 2009; Milne and Adler 1999) and its assurance (Ackers and van Heerden 2015; Adams and Evans 2004; Hodge et al. 2009). Therefore, the role of the external assurer becomes a key element for the credibility of CSR information that seeks to guarantee an adequate scope to meet the needs of stakeholders (Adams and Evans 2004). A commitment must be acquired with the stakeholders to guarantee information transparency and encourage their participation in the assurance process (Park and Brorson 2005). The assurance provider must know and understand the relationships between them and the company, from which CSR criteria included in a sustainability report have been developed to determine aspects such as relevance, materiality, comprehensibility, and integrity (Bebbington et al. 2007; Manetti and Becatti 2009; Wallage 2000).

Despite the prominence that stakeholders should acquire throughout the process related to

firm sustainability, doubts arise concerning their true inclusion in assurance processes (Ackers and van Heerden 2015; Manurung and Basuki 2010; O'Dwyer and Owen 2005). The absence of regulation in this market allows managers to decide which information should be verified and, if the result of the assurance is published, which favors managerial capture. This concept refers to the fact that managers can take control of assurance policies and practices, pursuing their own interests or those of a particular group, instead of seeking utility for all stakeholders (O'Dwyer 2003; Smith et al. 2011). Given this situation, the assurance service can be seen from a symbolic perspective, to manage stakeholders' perceptions (Michelon et al. 2015), and CSR disclosures can become a controlled public relations exercise (Owen et al. 2000). This circumstance diminishes the clarity and transparency of the assurance statements, causing a negative impact on the mechanisms of accountability (Deegan et al. 2006) that reduces the public interest of this service (Smith et al. 2011). Therefore, while stakeholder inclusiveness is a key element of external assurance quality (IFAC 2011), it is also one of the major difficulties that the service and its market face (Manetti and Toccafondi 2012).

Summary

The new concept of transparency that emerges with the CSR paradigm establishes the need for companies to issue reliable information, beyond the financial scope, that supports the stakeholder decision-making processes. This need encourages the demand and the offer of assurance services for sustainability reports and, consequently, the creation of its market.

The configuration of this market has a certain parallelism with the financial auditing market. Both have a common justification: the need to increase information credibility. Thus, three different participants are identified: the companies, which constitute the direct demand of the service as information transmitters; the service providers, who are delivered with the opportunity to provide their professional services in a "fertile

Assurance Market,**Fig. 3** Assurance market: configuration and particular characteristics

A

area”; and users, who increase their confidence in the information to be able to make decisions through assurance. However, the development of the assurance market of sustainability reports is conditioned by two factors that distinguish it from financial auditing: the absence of legal requirements regulating the service and the large number of information addressees. Figure 3 graphically represents the structure of the external assurance market based on the auditing market scheme. It reflects how the two mentioned characteristics condition the rest of the participants.

The absence of legislation causes the existence of demand of voluntary nature. Taking into account the predominant characteristics of the companies demanding the service (large size and belonging to sensitive industries), this demand can be explained by the legitimacy theory and, therefore, by the pressure the users exert on informant companies.

No legal provisions regulate a specific profession in terms of the offer. Multiple suppliers compete in this market where large professional service firms are predominant. They can offer the multidisciplinary teams required by the complexity of nonfinancial information. However, its ability to increase users’ confidence ultimately conditions the quality of its services, which makes it indispensable to include stakeholders in the assurance process.

Finally, both the absence of regulation and the broad number of stakeholders can lead to non-compliance with user expectations, thus distorting the public interest of the assurance service. This circumstance would justify the appearance of regulatory initiatives that would, in turn, be hampered, among other issues, by concrete public interest in the face of different needs and types of stakeholders.

In short, the assurance market for sustainability reports (and any other means of communicating nonfinancial information) is an emerging market in its early stages of development. Its operation could be considered in parallel with the auditing market, due to the similitude of both services. However, despite the growing demand for the service by greater and more sensitive firms, and the existence of a set of different professionals providing it from a multidisciplinary perspective, its particular characteristics have impeded its development with the same rigor as its counterpart in terms of regulation and, therefore, public interest protection. However, just like the regulatory framework regarding CSR communication is evolving, the assurance market is expected to eventually do so too.

Definition

The audit is a complex, objective, independent, and inductive process, and it has a clear objective to verify if the activity is performed according to its efficiency and performance criteria and by internal and external regulations. The audit is a monitoring mechanism that helps managers to make efficient decisions if the auditors are specialists and do not have any relationship or conflict of interest with the organization audited. The audit definitions should be adapted to the challenges of digitalization and the pandemic crisis generated by COVID-19. Therefore, the audit can be defined as a process that uses the advantage offered by digitalization to develop the capacity of the audited organization or activity to overcome the internal and external obstacles and improve their performance.

Introduction

The financial audit was at the origin of the audit. However, the diversification of the activities developed many typologies of audit: cultural audit, quality audit, project audit, social audit,

human resources audit, IT audit, security audit, and many others.

The landmark in the audit process, no matter its typology, remains the financial audit, and, as a control tool, the audit is perceived as a process that requires much time and human resources.

The audit is performed by auditors who use qualitative and quantitative techniques to develop independent reasoning, referring to the rules of evaluation, reliability, or efficiency of an organization's systems and procedures concerning standards (Burlea-Schiopoiu 2008).

The auditors should continuously find the answer to the following questions:

How can we improve the image of the audit and transform it from something frightening into a strategic tool of the organization?

Why is the audit considered a punishment and a source of criticism?

The audit results consist of internal or external audit reports. The managers and employees of the audited organization perceived the recommendations as a critique and not as tools that provide organizations with valuable information for improving the weaknesses and developing a creative organizational climate (Bogdan 2021).

The image of the audit can be improved by establishing a balance between strengths and weaknesses or the risks of the organization or activity being audited. Therefore, the audit aim will be aligned to new challenges, and it will consist of transforming the essential information and procedures in instruments of sustainable change that require continuously corrective actions that will improve the organizational performance.

Digitalization, dispersal, and the contradictory sources of information are factors that negatively influence the audit by a considerable amount of data that requires additional skills of auditors. In this framework arises the following question:

How can auditing be transformed from a time-consuming and resource-intensive process into an efficient and flexible process?

We will find the answer to this question in the following sections.

Key Issues

The Audit: From Control to Recommendation

The relationship between risks, fees, and efforts in the auditing process is critical, and its disequilibrium generated by omitted or incorrect information is considered a source of many scandals. The efficiency of audit consists of objectivity and independence of the auditor and is based on information available and practical regulations. Moreover, the auditors observe, critically analyze, and evaluate the organizational weaknesses and the strengths during their mission to evaluate the risks and elaborate the recommendations considering the organizational particularities and the external environment.

Zhang and Shailer (2021) observed that the audit fees significantly increase when new risks of material misstatements in extended auditor's reports appear. This correlation between extrinsic motivation (audit fees) and the auditors' responsibilities partially explains the subjective or objective behavior of the auditor.

The financial and ethical pressure makes the auditor give the audit process a negative image and emphasize its control side.

The solution for transforming audit from control to recommendations consists of the auditor's total independence from the audited organization and correlating the workload with auditor salary. Therefore, the audit fees should be established, considering the particularities of audited organizations and auditor competencies. An audit process flexible and objective results from the balance between audit risk and audit outcomes.

The Impact of Dispersal of Information on Audit

The dispersal of information (DI) "is described by a large amount of information that is presented chaotically and repetitively," and it is ubiquitous in the audit process proved by many criteria that classify the audit (Burlea-Schiopoiu 2019, p. 142). The diverse typology of audit creates confusion for both auditors and organizations. DI is promoted by managers who overestimate

their position in the organization and transform their decision-making process in an attribute of auditors. Therefore, DI allows the managers to transfer the responsibilities related to their unethical behavior to auditors and limit auditors' independence. The auditors' independence is related to the information they need and audit fees (Burlea-Schiopoiu and Idowu 2016).

The other source of DI consists of auditing standards that do not clearly specify how the auditor will make the difference between omitted or incorrect information and the disclosed information. The auditor should assess the quality of information, formulate an objective opinion on existing information based on organization systems, and neglect the financial pressure to avoid repetitiveness of disclosures over time.

The Impact of Audit on Organization Ethics

The purpose of the audit is to assess the degree of involvement of the organization in promoting ethical principles and create value for it by promoting an ethical climate. The sources of many financial scandals were the unethical behavior of the organizations and the weaknesses of the audit process. Therefore, it is essential to understand the regulatory environment and the particularities of audited organizations very well because sometimes the past ethical or unethical behavior can be reflected in the current behavior and the revealed information related to fraud risk assessment.

The auditors should improve their professionalism and objectivity when the audited organization has problems and pay great attention to falsified documents and records. Auditors' independence should be analyzed with audited organization financial statements and ownership structures.

Managers have incentives when they hire auditors who easily give up their independence and this unethical behavior is predominantly reported to managers that by their influence on the decision-making process, equality between their interests and shareholders'.

Another cause of unethical audit is managers' interests who want to exercise greater control over the organization and make decisions that no longer converge with shareholders' interests. This desire for supremacy of managers causes them to

falsify or hide some critical information from the auditor.

The solution for avoiding unethical behavior consists of a puzzle strategy in audit that requires an auditor for every piece of the puzzle and, at the end of the process, an auditor who was not involved in the initial audit process to solve the puzzle and write the report.

The puzzle strategy required regular interaction between auditors and the board of managers to discuss the problems as they arise, elaborate on ways to solve them, and mention them correctly in the final report.

This puzzle strategy has many advantages as follows: the financial and time pressure on auditor is reduced and mitigates the threat to the independence of the auditor; the possibility to falsify documents and records is low because puzzle strategy audit supposes a concatenated analysis of information, and if a piece of the puzzle is not properly audited, it will lead to the resumption of the audit process by another auditor.

Future Directions

In the future, the digitalization of audit and the dispersal of information will raise other challenges, but the leading actor will remain the auditor that will make the difference between recommendations and critics. The organizations will increasingly be exposed to external risks, regulation abundance, and contradictory sources of information, which will require audits to be conducted at shorter intervals. The objectivity of the audit depends on the objectivity of the auditor. Therefore, auditors must develop their skills and audit skills. They must also have communication skills, strategic thinking, and empathy to identify the organization's weaknesses and provide the most effective recommendations to be accepted by both shareholders and stakeholders.

Summary

The audit is a complex process that involves all organizational departments. Due to the evolution

of technology, many audit tasks were digitalized, and the involvement of the human factor was reduced at the level of critical thinking and interpretation of the facts and documents. Digitization has added new competencies to the auditors and contributed to their independence. However, the dispersal of information is used by some auditors as an excuse for the low quality of their reports. Nowadays, the evolution of audit is evident because if the process were seen as punitive, at present, the audit is considered as one that, by its recommendations, contributes to increasing organizational performance and improving work climate.

[Sustainability assurance](#); [Sustainability auditing standards](#); [Sustainability reporting standards](#)

Definition

Sustainability performance data has become a crucial decision-making criterion for investors. Due to the increasing relevance of nonfinancial information, in particular about environmental, social, and governance (ESG) aspects, sustainability performance data has become a powerful tool for both shareholders' and stakeholders' decision-making. Independent external assurance is a key way for increasing the credibility of sustainability reporting and, indirectly, of the companies' reported performance. External assessment of sustainability disclosure processes and reports can give users greater confidence in the quality of such data and therefore promote its

usage, as it is the case for historical financial figures. However, despite its relevance and materiality, and the increasing public expectation of accuracy of the information displayed in sustainability reports, assurance on these disclosures is not widely required yet. Sustainability reports are being voluntarily assured by an independent third party, and increasingly so; however, the level of assurance varies considerably due to the inherent characteristics of nonfinancial data.

Introduction

Investors are increasingly focusing on environmental, social, and governance (ESG) (4) dimensions of organizational performance, rather than only on financial and economic sustainability (3), when making investment decisions. To avoid multiple ways to communicate the information, as well as to enhance the consistency and comparability of sustainability reporting (8) and Corporate Social Responsibility reporting (2), sustainability frameworks have been developed (PwC, 2016). Entities have been making sustainability disclosures in their attempts to demonstrate accountability (that they are offering products or services with satisfactory sustainability performance by reducing adverse environmental and social impacts) and that they are contributing to sustainable social development (see, e.g., Ericsson's 2018 Sustainability and Corporate Sustainability Report – Ericsson, 2019). Such information is being communicated through press releases, companies' websites, and particularly through both voluntary and required sustainability reports, with the latter being the major source for ESG credibility. To support effective decision-making, sustainability disclosures must be not only relevant, comparable, and consistent, in the same way that it should be for financial data, but also reliable. As there is a risk of misleading or inaccurate ESG-related statements, ensuring their reliability becomes important. As a prerequisite for effective sustainability reporting, credibility can be considerably enhanced through independent external assurance (AccountAbility, 2008). This text aims to present an overview of

sustainability auditing and sustainability assurance (a broader concept of verification used for nonfinancial data), as a way to enhance the quality, usefulness, and reliability of ESG information (GRI, 2013) (5).

Sustainability Reporting Frameworks and Disclosure Requirements

Should sustainability reporting standards not exist, each company would produce the information at its own discretion. Criteria for evaluating performance information can be either established or specifically developed. Sources for established criteria may be regulatory requirements and other standards or frameworks, such as financial reporting ones. With regard to sustainability-related matters, specific criteria have also been developed and several organizations have provided frameworks for sustainability reporting and metrics as a guidance for companies to disclose such matters.

GRI's framework remains the most widely adopted global standard for sustainability reporting (KPMG, 2017; The Conference Board, 2018). In the USA, the Sustainability Accounting Standards Board (SASB) has issued guidance for disclosing sustainability metrics at an industry level, enabling investors and companies to compare performance across companies within a given industry. These standards only address the subset of ESG factors likely to have material financial impact on a company, which vary by industry. Some companies have started to complement GRI's approach by considering the SAS (e.g., Gap Inc., which has reported in accordance with SAS in 2018). Recently, the International Integrated Reporting Council (IIRC) developed the Integrated Reporting (IR) (6) framework, in which companies integrate sustainability reporting within their annual financial report. Demand from a variety of stakeholders, as well as the introduction of regulatory requirements in some countries, has promoted companies to make climate change-related disclosures and promoted the development of standards for certain types of information, particularly Greenhouse Gas (GHG)

emissions. The Carbon Disclosure Standards Board (CDSB) developed the Climate Change Reporting Framework (CCRF), enhancing standardization and consistency of climate change-related disclosures in financial reports (CDSB, 2012). In summary, and in spite of the availability of several frameworks and some tendency toward adopting the GRI framework, there is no single generally accepted reporting standard and no single set of criteria to measure and report sustainability information. Given the lack of comparability between entities' criteria, these need to be clearly disclosed so that users can understand how the reported information was measured, recorded, collected, and reported (IAASB, 2013).

Nonfinancial data, in the past only disclosed voluntarily, are now required for companies operating in several countries, namely in the European Union. The European Directive on Non-financial Disclosure, Directive 2014/95/EU, established the requirement for public companies with more than 500 employees operating in Europe (including non-European companies) to report on multiple nonfinancial metrics. Topics to be disclosed include environmental protection, social responsibility and treatment of employees, anti-corruption and bribery issues, as well as diversity of their board of directors. Regulators in other regions have taken a similar approach, and ESG disclosure has become a listing rule in multiple stock exchanges, such as India, South Africa, and Brazil (Singer, 2018).

Assurance Needs on Sustainability Reporting

With the proliferation of ESG information reporting and practices, it has become clear that external assurance would be of interest to investors in assessing the reliability of such reports. Therefore, the increase in sustainability reporting has been accompanied by a growing interest in the accuracy of such reports and by demands of assurance statements to be included in the sustainability reports.

“External assurance or verification can provide both report readers and internal managers with

increased confidence in the quality of sustainability performance data, making it more likely that the data will be relied on and used for decision making” (GRI, 2013). Reporting assurance is the practice of using an independent third-party verification for data included in the report and for the process behind such report, in accordance with specific assurance standards. “Auditing” is a part of the wider “assurance” term, although they are often used interchangeably. Although both consist of the external verification of data to provide confidence on disclosed information, they are separate concepts. The key difference relates to the conclusion being or not an objective opinion on that data. Auditing usually applies to audits of historical financial information based on auditing standards, while assurance is used for the remaining situations, such as sustainability reporting.

There is a significant increase in the number of companies choosing to have their nonfinancial data externally assured. According to the analysis by the Conference Board (2018), sustainability report assurance is used by almost 40 percent of S&P (Standard & Poor's) Global 1200 companies, with European companies furthest ahead in adopting ESG assurance, namely when compared with companies in North America (Singer, 2018).

Assurance Standards for Sustainability Reporting

Unless there are criteria that are suitable (relevant, complete, reliable, and understandable) for evaluating specific performance information and against which the assurance provider performs testing procedures as part of its approach, no assurance may be given (IAASB, 2013). One of the major difficulties in providing assurance on sustainability reports has been concerns about the development of generally accepted reporting criteria for nonfinancial data that are suitable across companies and even industries. As criteria used to measure sustainability matters are not widely established and are frequently specific to a particular entity, properly defined and disclosed

criteria are a fundamental requirement to be able to provide assurance.

Several standardized approaches for assurance on sustainability reports have been developed (7). Assurance frameworks and standards provide guidance to be used during the assurance process, similarly to international auditing standards for financial reporting audits. Major standards and guidelines for sustainability reports assurance are the International Standard on Assurance Engagements (ISAE) 3000 (Revised) and AA1000 Assurance Standard (AA1000AS) (Rao, 2017). The Big Four firms, traditionally involved in financial audit, appear to favor the use of ISAE 3000 (Revised), issued by the International Auditing and Assurance Standards Board (IAASB) of the International Federation of Accountants (IFAC), individually or together with AA1000AS, rather than using AA1000AS individually. Other specialist assurance providers appear to be more comfortable using AA1000AS (Rao, 2017). The assurance parameters given in ISAE 3000 (Revised) are similar to traditional financial statement auditing and are based on a risk and assertions approach, together with sampling testing. Assurance procedures may also consist of inspection, observation, confirmation, recalculation, reperformance, analytical procedures, and inquiry, in order to gather evidence supporting the selected information in the sustainability report.

Given the increasing importance of climate change issues and their link to GHG emissions, many companies are quantifying their GHG emissions for internal management purposes. Many are also preparing a GHG statement as part of a regulatory requirement or in the context of an emissions trading scheme, or to inform investors and others on a voluntary basis. The ISAE 3410 deals with assurance engagements to report on an entity's GHG statement, setting out constituent elements and quantifying GHG emissions for a certain period (IAASB, 2012). This specific assurance standard enhances the strong demand for assurance of GHG emission reports. Finally, the International Organization for Standardization standard ISO 14064-3:2019 also provides guidance for verifying and validating such statements.

There are differences in terms of the extent and the depth of the assurance (the scope), and the

wording of the conclusion of the verification will differ accordingly. An important step in the assurance approach is defining what is to be externally verified, in terms of the disclosures (whether the whole report or only specified elements) and the processes or systems related to sustainability. Depth may be greater (reasonable assurance) or lower (limited assurance). In a reasonable assurance engagement, the conclusion is expressed in a positive form; it states an opinion on the outcome of the measurement or evaluation of the underlying information against given criteria, and it states that the information is free from material misstatements (IAASB, 2013). On the contrary, in a limited assurance engagement, the conclusion is expressed negatively. Such approach is restricted to inquiring, primarily people responsible for preparing the sustainability report, and applying analytical and other limited assurance procedures, rather than examining, on a test basis, evidence supporting the information being assured. However, in accordance with ISAE 3000 (Revised), a combined approach may be used.

Although, as mentioned above, sustainability reporting regulations are increasing and several regulators and exchanges have taken initiatives to promote disclosures on ESG performance (e.g., the recent requirement by the European Union Directive 2014/95/EU to verify the disclosure of nonfinancial data), sustainability assurance is not widely mandatory or regulated. No regulator recommends adopting any particular assurance framework or any particular type of assurance scope; in addition, providers can freely select any of the existing options. Finally, there is no specific requirement either with regard to the sustainability assurance provider, which may originate from the auditing (accountancy) profession or from outside (sustainability services and engineering firms). Major providers are, however, accountancy firms (GRI, 2013) (1).

The Current Status and the Future of Sustainability Assurance

In spite of the increase in assurance demands, the scope of ESG assurance is still narrow and restricted by most companies to a limited number

of ESG indicators (Singer, 2018). This study also reveals that in a few examined companies the scope of assurance only included the data collection process and methodology, but excluded verifying the data itself. Moreover, the majority of ESG data within the scope of the assurance was related to GHG emissions; beyond GHG emissions, the scope mainly included metrics focusing on energy and water consumption (Singer, 2018). These findings are consistent with the nature of sustainability disclosures, involving a mix of quantitative and qualitative data. Furthermore, quantitative sustainability disclosures are usually not measured in monetary units, and internal control procedures and data collection processes may lag behind systems and processes for financial reporting (GRI, 2013). Sustainability reports to be assured may also address a wide range of areas such as the environment (GHG emissions, waste recycling or water usage), health and safety, social responsibility, and governance structure. In addition, much of the quantitative information for different data is not measured in a common unit of measure. For example, customer satisfaction performance indicators may be measured in terms of customer complaints, while injuries/illnesses may be measured as a percentage of working hours. With such a variety of sustainability data and measurement units, alongside qualitative information (often with equal importance to users as quantitative information), current assurance methodologies, based on monetized measures, need to adapt to ensure a high-quality sustainability reporting.

Instead of expanding the scope of their ESG disclosures, firms are turning to focus on sustainability issues considered to impact their business in a more material way (Singer, 2018). As such, business materiality is increasingly privileged when selecting reported metrics. For example, carbon emissions are more material to a manufacturer than to a financial institution. It may be challenging for a company to determine which sustainability indicators are material and decision-useful for the market, to define appropriate processes to capture such information and to define controls to disclose them reliably (PwC 2019). Challenges are likely to be even greater for the assurer when conducting its own

materiality assessment, an important step in the assurance process, and require specific knowledge of the sustainability issues for each industry and each company.

Environmental and social issues, such as climate change, water scarcity, and human rights, are expected to be increasingly seen as financial issues, rather than as nonfinancial ones, leading to a merger of financial and nonfinancial issues (KPMG, 2017). To a better understanding of the various ESG issues that may be faced during the assurance process, increasing expertise in both sustainability and assurance frameworks and practices is also desired. As there are different subject matters (such as environmental, labor practices, social, and human rights, among others), multidisciplinary teams are fundamental for an effective assurance approach, as well as the involvement of many experts, as stated in ISAE 3000 (Revised) and 3410. The integration of financial information (subject to a mandatory audit) and nonfinancial information (that can be assured on a voluntary basis) may also result in additional challenges. In fact, the audit report on the financial statements and the assurance report on the sustainability information, potentially with a different assurance scope, are presented in the same integrated reporting, hence potentially creating confusion among users.

To overcome the practical issues in assuring in accordance to ISAE 3000 (Revised), the IAASB has initiated in October 2017 the “Extended External Reporting (EER)” (integrated reporting, sustainability reporting, and other reporting by entities about ESG matters) assurance project (IAASB, 2019). The purpose of this project is to provide practical guidance for the implementation of ISAE 3000 (Revised), namely, with regard to the suitability of the criteria and the materiality process discussed above. The final guidance is expected to be concluded in late 2020.

Summary

In the context of an increasing relevance of non-financial data, sustainability reports are being widely publicly disclosed and investors are

increasingly integrating ESG factors into their analysis. Therefore, akin to financial reporting, assurance of those reports has become a matter of public interest. Independently of the process and framework underneath the sustainability disclosures, those that are externally assured are seen as more robust and more reliable (GRI, 2013). External providers of independent and nonbiased assessment of the content of such reports have increased and the assurance process has become an important, although voluntary, factor in the organizational approach to sustainability. However, challenges exist. While what financial reporting is intended to measure is clear and related reporting practices are duly regulated and widely understood by users, sustainability reporting includes a diversity of matters and most relevant issues to be measured and disclosed vary by sector, and even by company, and involves a mix of quantitative and qualitative information. While auditing financial information is widespread and required for large companies, assurance on ESG and global sustainability reports is still developing the most appropriate and effective assurance methodologies for assuring sustainability features, which cannot be quantitative or monetized. While harmonizing frameworks and metrics to achieve greater consistency and comparability across reporting entities is important (PwC 2019), establishing requirements for assurance should also be a priority, in order to protect investors and other stakeholders from misleading and inaccurate ESG and global sustainability information.

Auditors and Corporate Governance

Adebimpe Lincoln
Law School, University of Liverpool,
Liverpool, UK

Synonyms

[Audit committee](#); [Audit risk and internal control](#); [Corporate governance control systems](#); [External auditors](#); [Internal auditors](#)

Definition

The audit function is a key internal and external corporate governance control mechanism. In recent times, the audit function has become one of the cornerstones of corporate governance because it provides an objective check on the manner in which financial statements are prepared and presented by firms (Cadbury Report 1992). This view is supported by Filatotchev et al. (2006) who identified drivers of good corporate governance to include independence of external auditors and a competent audit committee.

An auditor is someone who examines a firm's annual report and accounts to ascertain whether they have been prepared appropriately. The auditor is tasked with providing an accurate portrayal of the true nature of financial data and the financial health of the business. Auditors may be individuals or firms. They must be appropriately qualified and must be a member of a recognized supervisory body and meet independence requirements (Hannigan 2018).

There are two main types of auditors, namely, internal and external auditors. Internal auditors are relevant because they examine financial statements and consider wider issues such as firms' reputation and growth, and its impact on the environment and employee relations (Mallin 2019). Internal auditors are good internal corporate governance mechanisms because they bring

independent, objective, and constructive perspective to firms (BCBS 2010, 2014). External auditors are independent of the firm. They are good external corporate governance control mechanisms because they protect shareholder and stakeholder interests by acting as firm watchdogs and help reduce information asymmetry between management and stakeholders (Elon and Gynes 2003).

Introduction

Various corporate governance codes call for high levels of disclosure and transparency in firms. The objective of transparency is to ensure that shareholders and other stakeholders are provided with sufficient information necessary to ensure that they can effectively monitor the effectiveness of the board of directors and executive management (BCBS 2014). The disclosure of relevant and useful information, such as the selection processes for directors, ensures that stakeholders can hold the board of directors and management accountable for their actions (BCBS 2014). Transparency is essential for sound and effective corporate governance, because inadequate transparency practices ensure that shareholders and other relevant stakeholders and market participants cannot effectively monitor and properly hold boards and senior management accountable for their actions (BCBS 2014). Thus, the objective of transparency is to provide stakeholders with critical information necessary to ensure that they are able to assess the effectiveness of boards and senior management (BCBS 2010). Accordingly, the OECD (2004) posits that firms should produce written reports summarizing its mission statement and main objectives, performance, future plans, strategies, and exposures to risk. It also recommends that timely and accurate disclosures must be provided by firms of all matters, including its financial situation, performance, ownership structure, and governance to shareholders and other stakeholders. Therefore, a narrative report supporting the financial and audit report must be published, which should include the chairman's statement, the director's report, a corporate governance

report, a remuneration report, and increasingly a CSR and sustainability report (Tricker 2012).

Every company must appoint an auditor or auditors, except when the directors decide otherwise on the basis that audited accounts are not necessary (small companies are audit-exempt). In the case of public companies, where an auditor is to be appointed, the appointment must be made at the accounts meeting. Where the company is a public interest entity with an audit committee, the audit committee must make a recommendation on the appointment of the auditor to the board (Hannigan 2018). The audit committee is an integral corporate governance internal control system, it is a subcommittee of the board of directors comprised of independent nonexecutive directors (Mallin 2019). The audit committee helps in framing policy on internal audit, it oversees the financial reporting process, providing oversight of and interacting with the firm's internal and external auditors (BCBS 2015).

Internal Auditors and the Internal Corporate Governance Control System

Internal auditor ensures the effectual operation of governance and risk management as well as other internal control processes of firms (BCBS 2010, 2014). Therefore, internal auditors are tasked with matters that are of fundamental importance to the subsistence of the firm and its overall performance (BCBS 2010, 2014). According to Mallin (2013), boards and audit committees look to the internal audit function to:

- Provide a continuous analysis of the effectiveness of processes and associated internal control systems.
- Review operational and financial performance.
- Assess the achievement of corporate objectives.
- Identify areas of reform for the proficient use of resources.
- Confirm the existence and value of firms' assets.
- Carry out ad hoc inquiries into possible irregularities and fraudulent activities.
- Review the compliance framework and identify issues.
- Review firms' values and code of conduct or ethics.

The internal control system should ensure compliance with applicable laws and regulations and also seek to ensure reliable financial reporting and achieve operational efficiency. To ensure that internal auditors perform their functions they should be individuals who are independent and competent and possess personal integrity. The head of the internal audit should be a top manager (i.e., assistant general manager and above) and should be a member of a relevant professional body. The head of the internal audit is charged with ensuring that quarterly audit reports are conducted and provided to the audit committee. The importance of internal auditors was reemphasized in the 2007–2008 financial crisis. It was revealed that internal auditors were negligent because they had not considered the impact of a rapid national economic decline on banks and they had also failed to emphasize aggressive provisioning against risk assets (Lincoln et al. 2017, 2019). Mallin (2019) argues that in order to maintain independence and foster direct reporting relationship, it is best practice for a private meeting to be convened between the internal audit head, audit committee, and the board of directors.

External Auditors and the External Corporate Governance Control System

External auditors can detect and prevent fraudulent activities and assist in installing effective accounting systems in firms. The audit of financial statements ensures the credibility of disclosed information, thereby instilling confidence in firms' transparency (Tricker 2012). External auditors also ensure board and management accountability to shareholders and other stakeholders, which ultimately promote domestic and foreign investor confidence in the market (Mallin 2019). Consequently, it is essential for external auditors to be independent of boards and management. Lack of auditor independence is detrimental to the audit function and to achieving effective corporate governance. For example, the collapse of Enron was attributed to ineffective auditor oversight caused by a lack of independence (Elon and Gynes 2003).

To ensure independence and objectivity, it is essential that a professional relationship is maintained between external auditors,

consultants, internal auditors, and the management. External auditors must maintain a professional relationship, “present a fair, balanced and understandable assessment of the company’s position and prospects and establish procedures to manage risk, oversee the internal control framework, and determine the nature and extent of the principal risks the company is willing to take in order to achieve its long-term strategic objectives” (FRC 2018).

Various national codes have advocated that auditors should not simultaneously carry out auditing and consultancy functions in the same firm, this ensures that the audit process is not potentially corrupted by an auditor’s interest in obtaining consultancy fees (Mallin 2019). To ensure that financial statements accurately reflect risk management practices, internal controls, and compliance with regulatory provisions, the UK Companies Act (2006; Sec 485(1), 489(1)) and the Corporate Governance code 2018 mandate that such reports are externally audited. External auditors must possess high integrity, independence, and competence (FRC 2018).

Key Issues

Audit, Risk, and Control Function

The Corporate Governance Code (2018) advocates for audit, risk, and control functions. The Code lists three principles which focus on the internal and external audit function; balanced and fair assessment of the company’s position and prospects; risk management procedures and internal control framework. The Code states that “the board should establish formal and transparent policies and procedures to ensure independence and effectiveness of internal and external audit functions and satisfy itself on the integrity of financial and narrative statements” (FRC 2018). For example, the audit committee has a role in fraud prevention; as such it must ensure that there are provisions throughout the firm that allows transparent disclosure and report of improprieties. Furthermore, effective whistleblowing provisions should be provided.

Under the UK Corporate Governance Code, directors are mandated to “explain in the annual report their responsibility for preparing the annual report and accounts, and they must state that in their opinion, they consider the annual report and accounts, taken as a whole to be fair, balanced and understandable” (FRC 2018). In addition, they must provide pertinent information, which is required for shareholders to make an informed assessment of the firm’s performance, business model, and strategy (FRC 2018). Principle 26 of the UK Corporate Governance Code also offers greater safeguard by providing that the “annual reports should describe the work of the audit committee explaining how it has assessed the independence and effectiveness of the external audit process and the approach vis-à-vis the appointment or reappointment of external auditors. Furthermore, where there is no internal audit function, a clear explanation is required for the absence, how internal assurance is achieved, and how this affects the work of external audit” (FRC 2018). Finally, the annual report must clearly outline how the company was able to safeguard the independence of auditors, and their objectivity, where the external auditor provides additional non-audit services (FRC 2018).

Audit Committee Composition and Responsibility

The UK Corporate Governance Code advocates for the establishment of an audit committee. The UK also implements the European Union Audit Directive (2014/56/EU), which imposes a requirement for firms whose securities are traded on a regulated EU market to have an audit committee. This further shows the importance of the audit committee and steps taken both on a national and international level in ensuring this key function within the firm.

The audit committee should comprise a “minimum of three independent non-executive directors.” In the case of small firms, the audit committee should comprise a “minimum of two independent non-executive directors.” The chair of the board should not be a member. The board should satisfy itself that at least one member has recent and relevant financial experience. The

committee as a whole shall have competence relevant to the sector in which the company operates” (FRC 2018). Furthermore, in order to ensure collaboration in the auditing process, the audit committee should have access to external auditors for explanations and additional information without the presence of management (FRC 2018).

The audit committee is tasked with a robust list of responsibilities. Principle 25 of the UK Corporate Governance Code sets out the main roles and responsibilities of the audit committee. It states that the role and responsibility of the audit committee includes assessing the integrity of the financial statements of the company, advising the board of directors on the fairness of accounts and annual reports, scrutinizing the internal financial controls and risk management structures and systems of the company, and assessing the internal audit function of the company. The audit committee is also tasked with recommending to the board of directors the appointment and removal of external auditor, ensuring external auditor objectivity and compliance with any professional and regulatory requirements. Finally, the audit committee is tasked with devising policies where external auditors are required to provide non-auditing services and ensuring this does not encroach the auditor’s independence (FRC 2018). The committee must also report to the board of directors the steps taken to effectively discharge its responsibility (FRC 2018).

Summary

Good corporate governance mandates the introduction of internal and external controls mechanisms to ensure effective audit and risk prevention within the firm. So as to ensure they perform their functions effectively, auditors must be individuals who are independent, competent, ethical, and possess personal integrity. The internal control system should ensure compliance with applicable laws and regulations and also seek to ensure reliable financial reporting and achieve operational efficiency. In addition, the external auditing function should ensure board and management

accountability to shareholders and other stakeholders, thus promoting investor confidence. External auditors are important corporate governance players. They are gatekeepers, consequently, they must be independent, maintain a professional relationship, and ensure they effectively oversee the internal control framework within the firm.

The importance of the audit committee in ensuring effective corporate governance cannot be overemphasized. The audit committee is considered a key governance committee created to oversee the internal control framework of the firm. The committee is tasked with determining the nature and extent of the risks the firm is exposed to relative to its long-term strategic objective. The audit committee should be competent and have a clear understanding of the sector and industry in which the company operates. Finally, the audit committee should be responsible for reviewing the integrity of financial reports and overseeing the independence and objectivity of external auditors.

being oneself, and remaining true to one's self. Indeed, behaving authentically means acting in accord with one's values, preferences, and needs as opposed to acting merely to please others to attain rewards or avoid punishments through acting "falsely" (Kernis and Goldman 2006). According to this construct authentic leaders have been defined as those individuals who are deeply aware of how they think and behave, as well as of the context in which they operate. They are perceived by others as being aware of their own and others' values and moral perspective, knowledge, strength, and as being confident, hopeful, optimistic, and resilient (Klenke 2007). Authenticity is about being sincere, honest and genuine (Trilling 1972). When underpinning the entrepreneurial and managerial conduct authenticity represents a key element of the orientation toward genuine corporate social responsibility (CSR) and sustainability approaches that rest on a social, economic, environmental, and anthropological ecology. In other words, authentic CSR is driven by authentic leaders capable to orient the company toward the common good (Zamagni 1995; Kaptein and Wempe 2002).

Authentic CSR

Mara Del Baldo

University of Urbino Carlo Bo, Urbino, Italy

Synonyms

Ethically based CSR; Ideal-driven CSR; Intrinsic CSR; Non-opportunistic CSR

Definition

The concept of authenticity has been addressed in both religious and historical studies. Moreover, it has been extensively treated in various disciplines, including psychology and philosophy, among others. Authenticity calls us to be true and real to ourselves and the world (Terry 1993). The construct of authenticity refers to accepting,

Introduction

In the last decades business ethics literature has emphasized authenticity and integrity in the corporate context (Paine 1994; Vyakarnam et al. 1997; Hemingway and MacLagan 2004; Ketola 2008). Virtue ethics has gained momentum within business (MacIntyre 1985) attempting to ground ethics on the basis of character (Bertland 2009) and emphasizing integrity both at a personal and organizational level (Solomon 1992; Melé 2009; Bertland 2009). Rediscovering the strength of virtue ethics in the business environment contributes to foster best practices (Flynn 2008) since ethical-driven and purpose-driven businesses are addressed to pursue common benefits and construct a more civil economy (Carroll 2000; Driscoll and Hoffman 2000; Pruzan 2001; Argandoña 2003; Luthans and Avolio 2003; Zadek 2006; Riggio et al. 2010).

Nevertheless, CSR policies often fail in rendering organizations more ethical because they are not authentically driven and lack from a consistent leadership model (Painter-Morland 2006). The gap between leadership and effective CSR can be attributed to the fact that CSR strategies are often driven by extrinsic motivation and therefore are not adequately connected to an authentic ethical construct (Looser and Wehrmeyer 2015). Consequently, they cannot provide a lasting and effective contribution to sustainability nor do they trigger sustainable entrepreneurship. It thus becomes important to distinguish between extrinsic (opportunistic-led) and intrinsic (authentic and ethically based) orientation toward CSR and sustainability.

Business survival depends on a continuous endeavor for sustainability. In this context, a moral and virtues-based leadership is a key driver in implementing authentic CSR and sustainability-driven strategies, based on values such as caring, people-centeredness, integrity, transparency, and accountability (Garriga and Melé 2004; Visser 2011). Contemporary leadership literature emphasizes moral and ethical-based leadership as a prerequisite for effective leadership and many efforts have been devoted to identifying its content and antecedents (Brown 2005).

The attention that has emerged from the literature is confirmed in practice since there are more and more leaders who freely admit that they are driven by an intrinsic commitment to values. While some organizations do not contemplate the challenge of taking a leadership stance on CSR and sustainable entrepreneurship, there are a growing number of high-performing companies whose success rests on their leaders' commitment to ethics and values (Lamont 2002), capable to translate into successful CSR and sustainability strategies (Jenkins 2006). Those individuals (managers and/or entrepreneurs) engaging in sustainable entrepreneurship are doing so to leverage their authenticity in a way that contributes to broader social change. Therefore, attention is addressed to the antecedents of leadership models consistent to responsible strategies and practices pointing out the relevance of values and virtues in the entrepreneurial and business context. Values

and virtues are considered as “pillars” that act as “hidden” driving of CSR and sustainable orientation.

Key Issues

On the one hand CSR is either a commercial instrument and extrinsically motivated; on the other hand it is based on intrinsic (or idealistic) reasons, which makes it a moral activity. (Looser and Wehrmeyer 2015, p. 2)

Extrinsic CSR is aimed at increasing social legitimacy and company reputation (Matten and Moon 2008). Among the external drivers are contextual pressures from consumers, shareholders, competition, the media, international trade issues, or regulatory demands. More precisely, CSR engagement can be egoistic-driven by the desire to exploit a situation or strategic-driven by the goal of making a better profit and minimize risks. In addition, CSR orientation can be stakeholder-driven by the need to react to pressures from stakeholders. It usually manifests through a formalized approach based on the adoption of accountability tools (such as sustainability reports, ethical codes, certifications, stakeholder engagement activities) finalized to improve external recognition and market share. The extrinsic motives are consistent with managerial perceptions and beliefs that CSR is an effective tool to achieve wealth maximization, while financial performance is the actual financial status results. This approach often underpins a type of attitude in the use of CSR as a tool of rhetoric rather than an expression of virtuous actions (Visser 2011). It has been stigmatized as impression management (Hooghiemstra 2000) that ends up by crossing into phenomena of greenwashing, decoupling, and camouflaging (Laufer 2003; Moneva et al. 2006; Du et al. 2010).

Intrinsic CSR rests on entrepreneurial and managerial motivations related to morality, thus positioning CSR in a values-driven perspective (Looser and Wehrmeyer 2015) that sees CSR as the right thing to do and is consistent with an authentic approach to CSR. Hemingway and MacLagan (2004) signify the role that socially

responsible managers and entrepreneur can play as “change agents” because they can reflect their personal values regarding CSR on their managerial discretion and implementation of corporate strategies. Intrinsic CSR is thus consistent with responsible practices promoted by the entrepreneur and/or the top management (Lamont 2002; Jenkins 2006; Del Baldo 2012) and nurtured by authentic-driven relationships with internal and external stakeholders (Graafland and Van de Ven 2006; Graafland et al. 2012; Story and Neves 2015). “Authenticity is posited to be a function of the openness of the organizational climate and is manifest by the degree to which members resist personal change when enacting their leadership and professional roles. Organization’s authenticity is manifest through its leadership” (Gardner et al. 2011, p. 1121). “Organizational integrity means that the organization’s values should guide its interactions with internal and external stakeholders” (Painter-Morland 2006, p. 358). Organizational integrity manifests in organizational practices and relationships nurtured by values and virtues including justice, temperance, fortitude, and prudence, among others. In this regard, business ethics research emphasizes the role of contextual elements within the workplace in generating management and employee ethical behavior. The organizational context is interpreted as a direct influencer of individual moral or immoral action (Kaptein 2017).

Extrinsic CSR is mainly diffused among large companies, while small and medium-sized firms (SMEs) are more prone to manifest an intrinsically-driven orientation toward CSR (Wehrmeyer et al. 2020). Among SMEs and family businesses intrinsic motives are nurtured by personal and community values tied to the social capital they are embedded to. In such contexts, despite the lack of formal CSR strategies and extrinsic policies, CSR is ethically grounded. Accordingly, authentic leadership acts as a driver for social change, and the operationalization of CSR has the power to contribute to the common good by generating “social goods.” In other words, the “doing” CSR (the “walking”) is superior to communicating CSR (the “talking” of CSR) and hence CSR

practices should be the primary concern (Lee and Hageman 2018; Schoeneborn et al. 2019). In addition to SMEs, there are several companies where the aforementioned orientation is actually operationalized since they are purpose-driven, such as the economy of communion companies (Del Baldo and Baldarelli 2015), territorial companies (Del Baldo 2010), benefit corporations, and B Corps (Rawhouser et al. 2015), among others.

Future Direction

“Although there are important differences in terminology and foci, divergent perspectives converge on the acknowledgement that leadership effectiveness depends less on individual, heroic action and more on collaborative processes supported by a network of individuals, leaders, and followers engaged in collective achievement, teamwork, and shared accountability” (Klenke 2007, p. 69). Entrepreneurs and managers can trigger corporate responsible and sustainable strategies and hinder the “turbo-capitalism” effects (Matacena 2010) by valorizing people, relationships, the community, and the environment (Zsolnai 2015).

Some authors argue that the intrinsic motivation induces a stronger involvement in CSR (Graafland and van de Ven 2006). At the same time, several scholars claim for the need to adopt an integrative framework by considering the “mutually reinforcing relationship” among intrinsic and extrinsic CSR orientation (Muller and Kolk 2010, p. 4). A broader perspective concerning the intrinsic motivations of business organizations to pursue goals that go beyond economic performance and aim for long-term, sustainable performance is necessary. Such a broader perspective should take into account both managerial and entrepreneurial motivations, and the overall organizational context that influences internally the ethical activity of the organization, which can be further externalized and communicate as organizational (ethical, sustainability, and social) performance (Costantinescu and Kaptein 2020).

Summary

The “missing link” between the theory and practice of CSR and sustainability in the daily life of companies can be attributed to the lack of coherent and authentic leadership models and styles which should be consistent to a sustainability orientation and based on a moral and ethical construct. Adhering to these lines of thought, authentic CSR orientation can be considered a step in the business strategy (Schmidpeter 2014) that rests on a coherent leadership model. The latter incorporates transformational, charismatic, servant, spiritual, or other forms of positive leadership (Avolio and Gardner 2005).

Proactive entrepreneurial and managerial behaviors nurtured by authenticity contribute to orient businesses’ strategies and actions toward effective stakeholder orientation, transparency, and sustainable growth (Walker and Salt 2006). Running a company that is genuinely oriented toward CSR and sustainability requires a consistent leadership model based on values (such as justice and integrity), in directing the corporation so as to ensure its prosperity based on transparency, accountability, and responsibility (Von Ahnen 2015; Oreg and Berson 2011). A common trait of authentic CSR rests on the moral construct of entrepreneurs and managers, which generates the capacity to communicate the vision and strengthen a cohesive organizational culture, thus inspiring in others the will to emulate their choices (Hoivik von Weltzien 2014). Accordingly, a challenging approach Visser (2011) rests on the notion that business survival depends on a continuous striving for sustainability and that moral leadership is a key driver to implementing authentically CSR and sustainability-driven strategies.

Authority vs. Bureaucracy

Kristijan Krkač
Zagreb School of Economics and Management,
Zagreb, Croatia

Synonyms

Governance; Governance models; Leadership; Leadership models; Powers that be; Red tape

Description

Authority (from Lat. *auctor*, father, creator, one who brings about; and that from *augēre*, to create, Harper 2017), and bureaucracy (from Fr. *bureau*, office; and Gr. *kratein*, to rule, have power, strength, Harper 2017) are perhaps the oldest,

historically surely the most frequent, and nowadays the most practiced models of ruling and governance (important concept in *cratology*, i.e., the science of social power). The former simply says, the one who creates is the one who governs, while the latter says – since the governance is complicated because the system is complicated, no individual or a group can govern, rather the corresponding system of offices (*ruling of the offices*, Albrow 1970; Garston 1993; Weber 2015).

It should be noted that authority can be understood as the type of governance, i.e., governing authoritatively, and as a model of governance, i.e., authoritative governance, and so bureaucracy as well, namely, as a type, i.e., governing bureaucratically (say vs. administratively or corruptively), and as a model, i.e., bureaucratic governance (say vs. multi-authoritatively). It also should be noted that there are normative aspect of these models, namely, socio-psychological, cultural, and moral, i.e., ethical (Lynn 2006). There's some truth to it.

Introduction

On the one hand, the model of authority governance has its legitimacy in a common fact that the author of something has legitimacy and often legality to govern it, but authority governance can be understood and experienced as arbitrary egoistic autocracy, i.e., rule of the one or of the small body solely for their own individual benefits which hardly has any legitimacy what so ever from the point of view of the governed organization and its members and is considered immoral.

On the other hand, the model of bureaucracy, distinct from its historical development (Weber 1958), has its legitimacy again in a common fact that some organization's systems are too complicated to be governed by one or even a small group of people, rather they should be governed by the somewhat big group of very specialized professionals who govern all organizational actions, and all crucial standard operating procedures (SOPs), but as it can be the case, this model is such that these offices often turn to act solely and “arrogantly” (Merton 1957) for their own advantage,

something like a big net of closely interdependent small centers of authority, which again hardly has any legitimacy, and is considered immoral.

Concerning morality, it should be noted that no authoritarian model of governance is a dictatorship and that no bureaucratic model is oligarchy of egoistic bureaucrats by itself and so far immoral; rather they can be made immoral if they are misused as any other model. However, it is commonly suggested that these two models are extremely sensible to such misuse, among many reasons also because of the sometimes pessimistically understood human nature as essentially having certain propensity toward immorality.

As opposed to morality, authority (further on abbreviated as A) and bureaucracy (further on abbreviated as B) models of governance differ in many aspects some of which are nature (personal vs. impersonal), quantity (one vs. many), quality (one rule vs. complicated decision process), effectiveness (fast vs. slow), and social interaction, culture, morality (exclusive vs. inclusive). If A and B are understood solely as models of governance, they differ in their obvious formal features which make them more or less suitable for various types of organizations and various projects, and actions, so they are essentially good if used properly in appropriate situations.

For instance, if an organization faces an unexpected crisis due to some external causes none of which it contributed to, if a quick decision and action is of utmost importance, and given that A is much quicker than B, perhaps A is a more fitting model of governing than B. If, as opposed to previous example, an organization faces a long-term decision which will determine its future in say following 5–10 years, given that B is more systematic, rational, well-founded, all-inclusive, etc., then perhaps B is better than A.

On the one hand, there are negative connotations of A and B. Namely, an A without legitimacy is considered morally wrong because it is close to the authoritarian model of governance which is a type of totalitarian model as far as it unjustifiably limits human rights and freedoms. Further on, a B with clear and efficient administrative SOPs has, as it is commonly suggested, a natural tendency to become slow and illegal, i.e., performed

solely for the individual benefit of the administrators, which results with bureaucratization, and as such it is opposite to corruption. Obviously B can be morally wrong as well as A (Krkač 2013).

On the other hand, in themselves A and B have no negative connotations, especially not moral ones. There has been a series of suggestions for replacements of these terms, i.e., A with service, management, etc. and B with administration, jurisdiction, governing, ruling, etc. Historically speaking, what Weber called “bureaucracy” we nowadays call “administration” if it is public and management if it is private (like in corporations), and what was called “authority” we nowadays call “hierarchical governance,” “legitimacy,” and “legality” (for Weber see Waters and Waters 2015, especially concerning an English translation of German word *Herrschaft* as *rule* or as *authority*).

In what follows, A and B will be described, overviewed, and criticized, and their possible formal and practical conflict will be described in terms of various ways in which they are understood (Green 2013), since it is by all means possible that they are almost equally good and bad if used properly, i.e., in view of the goals of a given organization, or improperly, and they will be compared to different models of governance some of which are similar and some of which are quite different in order to show not only the variety of these models and the place of A and B among them but also to show that there are many possibilities in process of governance of an organization in most cases consisting of thousands of people, pieces of machinery, sites, periods, and processes.

On Authoritarian Model of Governance (A) and Its Criticism

History of archaic humans and modern humans show that a large amount of probably various authoritarian and anti-authoritarian societies existed in prehistory. Modern history shows the same thing, and there is no one dominant model of governing in history of mankind. In terms of political systems, it is a fact that democratic

systems existed previous to the French Revolution but only sporadically and locally (proto-democracy in small bands of hunter gatherers, for instance). It seems that an authoritarian model of governance was for sure not the only model but also that it was dominant. Given the fact that it has some obvious advantages over rival systems, such as speed of decision-making process, clarity of decisions, and swift execution, which was surely important in majority of history of the mankind which was for hundred thousands of years living without secured sources of water, food, shelter, without fire, etc., it seems obvious why the authoritarian model of governance was accepted and not challenged, namely, because it was efficient and it kept humans alive.

Having authority or not, being authoritative or not, or to rule in an authoritarian manner or not is a bit different thing. The first simply means that one has legitimacy and legality to independently decide on some matter and/or to perform an action concerning some issue. For instance, parents have authority over their children in terms of their biological, psychological, educational, and similar needs; or a teacher has an authority over pupils concerning their learning activities, etc. Having an authority doesn't mean executing it automatically. Omitting such execution for various reasons sometimes is also an example of authority, since only the one who has authority can omit its use. Sometimes an active non-use of the authority one undoubtedly performs is in fact the use of it, i.e., in the any case of toleration, since to tolerate means to have an authority over something or someone, and in the same time not using this authority (given that "to tolerate" means that A disagrees with what B does, A can prevent B in doing so, and A doesn't prevent B in doing so, see Walzer 1997). Lack of authority simply means lack of author or creator legitimacy or legality to decide or do something. Authority doesn't come in absolute terms, rather it has degrees.

Second, being authoritative means to act in accordance with an actual authority or as if one has it while one actually doesn't have it. The first is frequently used to mean to act over-authoritatively, especially in cases in which it is

unnecessary to do so, or to misuse an authority in terms of unnecessary intolerance or coercion. It concerns more the style of governing of an individual or sometimes the whole organization than the actual formal principles and SOPs of any type of governance.

Third, authoritarian ruling or governance is a formal set of principles and practices of governing of groups or organizations of various kinds, say family, group of friends, school, company, ministry, government, and even international organizations and non-governmental organizations (NGOs). It is of importance to understand that authoritarian governing isn't in itself a morally wrong thing to do. Namely, authoritarian governing doesn't mean authoritarian regime, rather simply the fact that in any organization, persons and offices in power perform their SOPs in accordance with the authority they have and without overstepping it with needed results which means that if they don't do it, it would be wrong. This shouldn't be understood as a misuse of authority for which there are further conditions.

Principles and Types of Authority Governance

Among principles of authority/authoritarian governance are the following: superiority of position of offices or individuals in power, hierarchy of organization, and top-down model of decision-making and execution. Obvious advantages are speed of decision-making process and implementation of decisions, while obvious disadvantages are firm structure which adopts slowly and lack of bottom-up communication which both can lead to the system corruption and failure.

Among types of authoritarian governance, from Weber onward, it is commonly differed between legal, traditional, and charismatic (Weber 1958). These types are strict, but they can mix between each other, so there can be various shared types (e.g., they can mix in time; a charismatic type can be followed by the traditional one). Types of legitimacy are differed in the same way, especially in Weber, as types of authority are.

The legality of authority rests on administrators who have legality and legitimacy by being appointed or elected as officials. In ideal model,

and Weber calls these types “ideal,” superiors are limited in their use of authority, but in actual system they are rarely so especially in a public administration (as, for instance, various corruption indexes show).

Traditional authority rests on the principle of inheritance. Inheritance doesn’t have to be biological, e.g., from father to son or mother to daughter, but it can embrace various relations, familiar, ideological, business/financial, between long-term friends, and similar (e.g., ideological and/or financial relations were quite important in the twentieth-century totalitarian regimes such as communism and socialism).

Charismatic authority is based on the personal charisma (gr. *χάρισμα*, *gift of grace*) of the leader or more rarely of the charisma of the whole group and all of its members (Weber et al. 2002). Charisma includes some special and unique qualities of an individual. This is the reason why still in many democracies, ex-generals, especially after wars, become ministers of defense, MDs become ministers of health, or lawyers or judges the ministers of justice.

In all pure types of authority, charisma is important, and it spreads over different social, economic, and political systems; namely, it seems to be trans-social, trans-economic, and trans-political. Nowadays in more or less free market economies and liberal political practices, we still have a lot of charismatic leaders and models of governance. They are manifested most vividly on various lists of top managers, the most influential politicians, intellectuals, celebrities, etc.

There is also a lot of misuse of charisma as a type of authority, e.g., it is often used if an appeal of an individual of some authority cannot be described clearly, while when it is explicated, charisma loses all of its explanatory powers and charm. Charisma is also a frequent buzzword and the same objection stands here as well. All meanings of charisma are metaphorical, while the only literal meaning is if it is “established” as a *gift by the mercy of Gods or God (per misericordiam Dei)*. Actually it is said that, if one says that a person is a charismatic leader, one has a mixture of appealing character, looks, charm, rhetoric,

motivational powers, and perhaps social status. Nowadays, a charisma can be constructed ex nihilo by various means, especially media, but destroyed as well. Here the so-called authority bias applies. It says that “there is a tendency to attribute greater accuracy to the opinion of an authority figure and be more influenced by that opinion” (Milgram 1963).

It is not correct that types of A and legitimacy do not have mixed types, because they do. It is also not correct that they follow each other irreversibly throughout history and that they present some kind of development. There is no proof that in a variety of circumstances and historical situations of societies, changes any of these types are the most efficient one, no matter what contexts may or may not occur internally or externally to a group or a society.

On Bureaucratic Model of Governance (B) and Its Criticism

From Weber onward, bureaucracy (B) refers to a system of government officials as elected or appointed on national or local level without whose activity the major public goals wouldn’t be achieved or to a system of administrative policy-making group, and such system is often large, dispersed, and extremely complicated (Weber 2015).

From its development and scientific research of it, from the nineteenth century onward, B is followed by its dark shadow consisting of a series of negative connotations. Some of these are an uncontrolled growth of a social system, the threat of self-purpose or becoming its own purpose without any purpose outside of it, slowing down public processes to the level of social collapse, emerge of corruption, bureaucratization, etc.

However, there is nothing in formal principles, SOPs, and normal functioning of B that suggests it will necessarily manifest these negative effects. Quite the contrary, B was invented with the purpose of eliminating these negativities that were manifested by often actually previous A systems of governance, and yet eventually it manifested them as well.

So, the major task of contemporary governance and managerial theories, policies, and practices is the reduction of B systems in quantity and developing it into more efficient and corruption-proof system of governance. In the same time, quality should be raised in terms of precision, time, effectiveness, etc.

Given the fact that contemporary governance systems, no matter if in global trans-national and trans-continental corporations or collaborations or in international public organization of any purpose whatsoever, are such that they cannot function without corresponding system of administration, the possibility of reducing B to zero is at the moment no option in reality and in day-to-day practice of such institutions. Why is this so, it remains unexplained, but common and yet not fully verified answer says that the bigger the organization is, the greater the tendency to be slower and ineffective (especially in view of Pareto, Kaldor-Hicks, allocative efficiency, and 80/20 principle).

One among obvious reasons is that contemporary organizations are not just too big to have big B, but also too complicated, so their Bs require a series of professions collaborating with the same goal. Some experiments and examples of the so-called holacracy (derived from “holarchy”) (see Koestler 1967) show that only partial reduction of B is possible in terms of hierarchical structure and self-organization. Some anarchical models show the same result especially if they tend to reduce all A and B. The major practical obstacle is the size of contemporary B system and their magnitude in terms of consequences of their actions. Alternative governing models work as far as they are applied to quite small organizations (families, small businesses, small local communities, and similar), especially social anarchism.

Principles of Any Types of Bureaucratic Governance

Weber saw that “an administration means fundamentally domination through knowledge” (Swedberg and Agevall 2005), and yet he saw its positive (rational) and negative (“iron cage”) connotations. Ideal B model by Weber is characterized by the following features: “hierarchical

organization, formal lines of authority, a fixed area of activity, rigid division of labor, regular and continuous execution of assigned tasks, all decisions and powers specified and restricted by regulations, officials with expert training in their fields, career advancement dependent on technical qualifications, and qualifications evaluated by organizational rules, not individuals” (Weber 2015).

Hierarchical organization is essentially bad in all cases in which a decision-making process should include equally important and regarded various stakeholders of an organization or an issue. If some of them are external, they by definition don’t belong to the hierarchy of B and are either excluded or included but as minor or undervalued stakeholders. If some of them are internal but low in hierarchy, their voice is practically rarely heard and taken as relevant.

Formality of B is an excellent feature in principle, yet if a decision has to be reached by a small group of superiors at the top of hierarchy, their informal relations forming at least in part their formal trust and professionalism can be important. Generally speaking, formality is much better than informality because it tends to reduce corruption.

Fixed area of activity is very important, but it is like Janus, a deity with two faces. It can be used properly in terms of subsidiary principle, but it can be misused in order not to perform regular activities and to meddle into something which doesn’t belong to B, especially if a B system tends to spread all over the organization and make it a purpose for its own existence and prosperity (in majority of cases of its own individual members).

Rigid division of labor also has two sides, namely, any division of labor is good because it is more efficient and effective, yet its over-rigidity can cause troubles particularly in rationalizations of members of B who didn’t performed particular part of the task and are removing the responsibility to some other often nearby members or groups of B.

Regularity and continuity of actions is by all means excellent feature of B as well as formality, since it is of utmost importance that some processes never stop no matter what, and B is capable

of sustaining these processes by these features (e.g., A doesn't have these features).

Regulative nature of activities is also two-sided feature because there is obvious risk of over-regulation of B procedures which are in practice frequently a sign of "bureaucratization" which means slowing down of standard speed of proceeding, lowering quantity and quality of results without obvious reason. Therefore, it is always good to draw a line below which there are no regulations in B, and above which as well, because processes belong to different administrative bodies (say elected ministers, prime minister, chief executive officers, and similar). Issues specific for B as a public administration are also important in this view because public administration because of its public legitimacy has a tendency to represent itself and to act as omnipotent ruler (Lynn 2006).

Officials with professional training create also important feature of B, since professionalism cannot be replaced, especially not with the so-called charismatic leaders as it is nowadays so emphasized by a series of managerial models and practices. However, professional bodies licensing future professionals are under the same risk as the whole B system, i.e., to become its own purpose and to serve its own superior members, and as such are open to corruption and especially nepotism and conflict of interest (professionals in some lines of work, such as outplacement companies in some European Union member countries, divided their professional organizations in several territorially based sections which mutually compete and therefore keep the healthy market and avoid these possible obstacles) (Noeleen 1998).

Authoritarian vs. Bureaucratic Models of Governance

Although A and B as systems of governance were historically matched to pre-democratic and democratic political regimes, and pre-free market and free market economies, this is just a historical coincidence. What is important in terms of their practical modeling or practicing is that A relies on a sole, individual, personal, and highest power of

one human being, while B relies on countless, plural, impersonal mass of officials who function as a supreme administrative body.

It is obvious that both A and B have some advantages and shortcomings, but comparatively B seems to be more suited for present-day purposes of post-modern living standards (e.g., inclusiveness on all levels, participation, equality, etc.) in contemporary societies and organizations (B seems to be a nice example of a model of governance which has inherent feature of refusing to be re-modeled).

Further on, they both prove to be incapable to solve their own problems that appear from their own improper application, use, and maintenance. A can easily end in authoritarian non-democratic and non-free market practices and B in self-absorbing system of bureaucratization, nepotism, and corruption.

There seem to be no internal tools in A and B to deal with these problems and misuses, so it seems that external solutions should be applied. However, which are they, nobody knows for sure, especially not the sociologists from the later twentieth century such as Merton who seems to see all the flaws in Weber's descriptions but offers no practical solutions (Merton 1957). Because of mentioned issues, the tension between A and B will continue to exist in the twenty-first century, but due to new circumstances, it is rational to believe in completely new forms in economy, law, and politics.

Summary

Authority governance isn't authoritarian governance, and bureaucracy governance isn't bureaucratization of governance, i.e., their negative effects; rather, they are value-neutral formal models of governance which proved themselves good in particular circumstances, but neither of them is universally good and useful.

This creates a particular tension between them and possible paradox on some levels of understanding and practice. Perhaps the twenty-first-century world as being more and more globalized in quantity and quality will present this tension in

a new light, especially on economic, legal, and international political levels, since as the world becomes more unified, it also becomes or at least needs to become more organized and efficient in order not to dismantle into small unrelated segments, and A and B are models of such organizations which are still the most frequent.

Yet, the old days, such as the twentieth century, in which these systems and models of governance were unchallenged are gone. New and alternative systems and models, while being invented in the twentieth century, are being applied in the twenty-first century, and some of them work at least at the level of small-scale organizations or groups within bigger organizations. This is certainly an external challenge to A and B both, and internal challenges are as old as human species, i.e., corruption, bureaucratization, etc., but they will, due to the fact that systems are becoming bigger than ever, create possible bigger problems that need to be addressed in the nearby future.

Awareness Management

Raisa Foster

University of Eastern Finland, Kuopio, Finland

Synonyms

[Management of awareness](#); [Organization's awareness management](#)

Definition

Awareness management is the process of leading an organization to gain and communicate a better understanding of complex issues with internal and external stakeholders that will then guide mutually beneficial transformations within the business, society, and the planet.

Introduction

Globalization has transferred power from political actors to those holding economic power. As a result, people's lives are affected more by the actions of large companies and business

innovations than by governments' decisions (Dicken 2003; Korten 1998). Rapid changes in the shifting of the center of power have caused new types of complex environmental, social, and economic problems to which it has been challenging to react efficiently locally and globally. Escalating environmental crises and human rights violations have led to perceiving the business sector primarily in a negative light: The private sector has been mainly seen as only producing social and ecological unsustainability, which should be curbed as soon as possible with stricter regulations and laws (Brinkman and Brinkman 2002). This interpretation has led, also within the business world, to see the goals of social and ecological sustainability as a burden and opposition to achieving the organization's financial goals (Alexander 2007).

According to Schaltegger and Wagner (2011), organizations' attitudes regarding sustainable development goals can be described through three categories. The first group includes organizations that oppose changes and view sustainable development goals as mandatory obligations. Such companies only strive to comply with the legislation and mainly aim for economic sustainability by reducing the production costs of their company. The second group includes organizations with an adaptive strategy that considers environmental responsibility a complementary part of their business. In these companies, operations are partly sustainable, but the importance of the sustainability of the business as a whole is not fully understood. Finally, the third category includes organizations with a proactive strategy, which means they have integrated sustainability into their overall business strategy and every individual operation. Such companies strive toward environmental and social sustainability in all their activities and understand that the sustainability perspective brings a competitive advantage for them in the market (Schaltegger and Wagner 2011).

Proactively responding to wicked sustainability problems requires skillful awareness management in organizations. Management must target both internal and external awareness of the organization, i.e., managers and employees and

customers and suppliers (Brem and Viardot 2015). Awareness management is not one-way administration. In contrast, increasing awareness moves from management to employees and vice versa, from the company to customers and from customers and other external stakeholders to the organization's internal stakeholders. The management of awareness requires systems thinking (Hossain et al. 2020), thus, a holistic understanding of how complex social and environmental issues are intertwined and how different interests and measures are connected. Awareness management based on systems thinking is also linked to recognizing and creating shared value (Porter and Kramer 2019) and even common good for all lives on the planet (Dyllick and Muff 2016). Increasing social and environmental awareness produces operations that mutually improve the company's success and the well-being of society and the environment.

Sustainability Standards

Sustainability management in organizations refers to the planning and implementing business processes so that environmental, social, and economic sustainability aspects are considered and continuously developed at every level of its operations (Gladwin et al. 1995). An organization often utilizes an extensive (e.g., ISO Management System Standards) or a more simplified system of standards to improve its operations. The concept of awareness management is typically linked to using a management standard because it helps to find ways to guide the sustainability awareness of the organization, particularly among its employees. A well-functioning standardized system does not only aim toward the awareness of harmful environmental and social effects but can also help to identify and reduce an organization's production costs. Furthermore, the standards help the organization to become more aware of how to put the sustainable strategy into practice. So, sustainability standards are organizations' practical management tools for sustainability awareness. The most well-known environmental management tools are based on the ISO 14001 standard,

ISO 26000 is a guide on societal responsibility, and ISO 9001 shows the requirements for quality management (see ISO 2022).

Applying a standard, the organization systematically considers environmental and social issues in all its activities. Standards can strengthen not only managers but employees' environmental awareness too and, through this, also help the organization's internal management, its continuous planning and monitoring of its operations in various sectors (Bettley and Burnley 2008). Moreover, a standard certification issued by accredited certification bodies can confirm the company's environmental and social responsibility to customers, partners, financiers, authorities, and media. So, the standards also help manage the awareness of the organization's external stakeholders by supporting its sustainable communication, branding, and marketing.

However, it has been identified that the standards are so detailed and complex that they are mainly suitable for only large companies. Smaller businesses are heterogeneous, and their processes cannot be easily scaled like large companies. Also, managing all the information necessary to evaluate the organization's sustainable actions is perceived as too complex. The correct selection, interpretation, and use of standards and indicators can be a challenge if companies lack proper resources and the personnel's awareness of diverse sustainability aspects is weak (Hillary 2004; Stubblefield Loucks et al. 2010).

Understanding that standards are helpful instruments but not end goals is also critical. Therefore, it is necessary to develop the organization's self-awareness skills and use stakeholder collaborations when identifying the true sustainability goals of a business. Then the choice of the best standards and indicators as practical development tools for this particular business is based on more broadly and systemically considered knowledge.

Organization's Self-Awareness

An organization's development efforts often remain isolated if sustainability issues are not

included in its strategy and decision-making at every level of its operations (Dyllick and Muff 2016). So, more than the administration of standards is needed to lead to the overall development of an organization; sustainability awareness and actions depend primarily on managers' and employees' genuine desire to rethink their values and develop operations. Sustainability transformation requires a critical self-reflection of individual leaders and laborers but also self-awareness of the whole organization and its role in society (Johnson 2015).

The starting point for an organization's development must be the understanding that business innovations change the world at least as much as state regulations. So, innovations do not happen by chance or by just obeying rules but require visionary leaders who decide and dare to act differently and place sustainability aspects at the center of the company's strategy and all of its operations (Esty and Winston 2009). Instead of just harm reduction, improving the life quality of society and the planet must be emphasized in sustainable business development (Dyllick and Muff 2016). Sustainable entrepreneurship means seeing the organization as an active and responsible agent in sustainable transformation (Dyllick and Muff 2016; Schaltegger and Wagner 2011). So, sustainability demands are not perceived as unfavorable but as positive catalysts for the business. Sustainable development means more than merely avoiding problems but solving them proactively with sustainable innovations (Schaltegger and Wagner 2011).

The challenge is making sustainability issues part of the company's strategy so that environmental and social responsibility are considered integral to all the company's activities. Furthermore, there is also a need for more clarity about how this happens concretely (Hillary 2004). Thus, awareness management is not just passing on knowledge in managers' and employees' training but integrating awareness and actions into the organization's everyday operations. Awareness is not raised just by pouring down visions from top to bottom but by generating conversations where everyone's interests, skills, and knowledge about sustainability are recognized, shared, and further

developed in cocreation between different management levels and between the leaders and employees.

Sustainable transformation does not happen without “creative destruction” (Schumpeter 1934; see Schaltegger and Wagner 2011). Therefore, the organization’s unsustainable practices must be first recognized and dismantled, and the underlying assumption of its production methods, markets, and consumer behavior must be radically rethought (see also Martusewicz et al. 2015). Then, creating novel markets for environmental and societal transformation that would also be financially sustainable requires an ability to imagine the organization’s more responsible relationship with the local and global community and present and future humans and the Earth (see also Berry 2012). Rethinking and undoing conservative values, structures, and practices do not only have to happen in start-ups but also through intrapreneurs who work in existing companies and are given space and time inside the organizations to develop innovative ideas that will enhance their future (Weber et al. 2014). However, an organization’s awareness does not improve merely in a vacuum but requires active communication also with its external stakeholders (Herzig and Schaltegger 2006).

Stakeholder Collaboration

A stakeholder is a party with whom the organization deals, which is affected by its operations, and which, in return, affects the company’s operations (Freeman 1984). Without stakeholders, the organization cannot function. There are various stakeholders inside (managers, owners, employees) and outside (customers, competitors, financiers, suppliers, authorities) the company. Stakeholders may have different goals for the company and its operations (Carney et al. 2011). For example, owners may want more profit, employees better salaries, and customers more environmental-friendly products. The various interests may result in stakeholder conflicts, which should be resolved with skillful awareness management. Awareness management must start from the understanding

that stakeholders always operate and communicate in reciprocal relationships that aim for sustainable value creation for all (Hörisch et al. 2014).

The concept of stakeholder value refers to creating optimum returns for all stakeholders in an organization, which is different from shareholder value, which usually focuses on maximizing the profits of the corporation’s equity owners. Creating Shared Value (CSV) is another concept that brings business goals and the community’s well-being together to benefit society. Therefore, successful awareness management begins with recognizing shared value creation (Porter and Kramer 2019). In its more radical form, it even aims for the common good of society and the planet (Dyllick and Muff 2016).

The organization’s ability to become aware of its place and purpose in society is a key to visioning and controlling its sustainability aims and operations instead of just being a passive object to external motivations, market demands, and authorities’ regulations. The organization’s awareness management is not a mechanical assessment of its strengths and weaknesses or just about green marketing and communication but an active and continuous interaction between the various stakeholders. In stakeholder collaboration, the organization shares ideas and searches for solutions with its internal and external stakeholders. They may have similar or different perspectives but always go beyond the different party’s vision of what is imaginable and achievable in terms of environmental, social, and financial sustainability (Hörisch et al. 2014).

When aiming for strong sustainability, the organization must thoroughly consider who its stakeholders are. Dyllick and Muff (2016) have presented that the sustainability transition of companies takes place through three typologies. The first transition toward a more sustainable business occurs when the organization recognizes not only financial but environmental and social sustainability aspects too as essential parts of its strategy. Therefore, the organization must expand its awareness by asking *what concerns* affect the company’s aims and operations regarding sustainable business development. The second transition

requires that the company understands that value creation must shift from shareholders to the Triple Bottom Line, so not only profit but also people and the planet. In other words, the organization must rethink for whom and *for what* they develop their strategy and create value. The third transition is a prerequisite for strong sustainability and requires the organization to change its perspective from inside to outside. When an organization asks itself *how* to implement a sustainable strategy that genuinely benefits more than just the organization itself, it must shift its primary focus to society and the Earth. In short, the organization must serve the planet's and people's needs, not the opposite.

This radical shift in an organization's awareness management toward strong sustainability, presented by Dyllick and Muff (2016), refers to an expansion of the stakeholder view to cover not only humanity now and in the future but also the more-than-human world (Abram 1996). According to this view, a stakeholder can be another human, or human community, another animal or an ecosystem, or even an inanimate nature, which is affected by the organization's operations, and which, in return, affects the company's operations directly or indirectly, immediately or in delay. This approach to awareness management extends beyond the anthropocentric worldview (see also Abram 1996; Keto and Foster 2021; Martusewicz et al. 2015).

Summary

In times of wicked social and environmental problems, the challenge of awareness management is to recognize the mutual relationship between social, economic, and ecological sustainability in the organization's values, goals, and operations. These aspects do not exist independently; success or failure in one area affects the state of sustainability in another area. Adopting systems thinking, the organization makes sense of the interdependent connections and the world's complexities by looking at them in terms of relationships rather than splitting them into parts and under the company's autonomous operations. Addressing sustainability issues requires

awareness management expertise in organizations. Management must target awareness of diverse, internal and external, local and global, and human and more-than-human, stakeholders in a way that is based on recognizing and creating the common good for all. Through transparent operations and open conversations, the organization can develop its self-awareness on the level of individuals and the whole organization and find its active role in creating a more sustainable society. An organization's success stands on understanding the cobenefits between the business and the well-being of human communities, societies, and the whole living Earth.

[Strategic scorecard](#)

Definition

A **balanced scorecard** (BSC) is defined as a management system, a framework designed for performance measurement at a strategic level for an entire organization. This solution was proposed by a team of 12 business representatives led by Robert S. Kaplan and David N. Norton in 1992 (Kaplan and Norton 1992). In their seminal paper, Kaplan and Norton initially referred the BSC as a set of measures divided into four interrelated categories: customer, finance, internal business, and (organizational) innovation and learning. Each of these perspectives addresses questions for management to answer. Their aim was to help to develop objectives, measures (KPIs), targets, and initiatives from the perspective of the identified categories. The customer perspective as its name implies takes the clients' viewpoint. The financial perspective includes a shareholders' perception of the organization's performance. The internal

perspective focuses on processes which should provide value for customers. The last perspective, the innovation and learning, aims at improvement and development. The linkage between all four perspectives culminates in a company's vision.

The framework described above was subsequently elaborated by R. S. Kaplan and D. N. Norton (1993, 1996a) by stressing a strategic dimension. The authors describe how applying a top-down approach allows strategic objectives to be deployed into lower management levels. Based on a cascading approach, the strategy (► [“Strategy”](#)) is not merely operationalized but more importantly aligned throughout the whole company. Implementing the BSC accordingly associates with translating the vision, communicating, and linking the company's objectives with individual performance, business planning comprising a financial budget supporting strategic planning, as well as feedback and learning to check if the strategy works (Kaplan and Norton 1996b).

Generations of BSC

A conceptual and methodological development led to the creation of the three main interpretations or generations of BSC (Lawrie and Cobbold 2004; Morisawa 2002). The first phase can be located between 1993 and 1996. During this period performance measurement was stressed as the main benefit of using the tool. The second

Balanced Scorecard,
Fig. 1 Logic of balanced
 scorecard and strategy map

BSC model and relations among
 perspectives

Strategy map

generation appeared in 1996–2004. Its main features included a strategy map. It was a new concept allowing the visualization of cause and effect relations among the elements included in the four categories. Overall, this helped to demonstrate how intangible assets serve tangible results (Kaplan and Norton 2004) (see Fig. 1).

Strategy maps can be used as a communication tool allowing for a better understanding of strategic management within a company. The third generation of BSC emerged around 2001 when the main use of this method shifted towards change management (Kaplan and Norton 2001). Succeeding generations continue to cover the earlier-mentioned strategy map and communication.

Key Issues

In spite of being used for more than 20 years, the use of the BSC is associated with some key issues which require consideration. The main ones include the need to adapt the tool to (1) suit the profile of the target organization and (2) address national culture.

The initial version of BSCs was designed for big corporations. Recognition of its benefits triggered attempts to adjust it to suit other types of organizations, such as NGOs (► “NGOs”) or public administration (Niven 2008). This resulted in the requirement to change the perspectives’

names, as well as adapting to a different logic in cases where money does not come from the company’s customers. For instance, the financial perspective may indeed be removed where shareholders do not appear as the main receivers of financial performance, as in the case of nonprofit organizations. To address this, a new categorization, group of donors (such as institutions giving grants, tax-payers, etc.), was introduced, while beneficiaries (e.g., citizens) replaced the customer perspective.

A further difference in the usage of BSCs originates from the requirement for national modifications. The literature distinguishes four distinct types. The first type represents the use of the original four dimensions related to customer, finance, processes, and learning. The second type characterizes a change in dimension type. An example of this adjustment is Skandia’s Navigator (Ax and Bjørnenak 2005). This insurance company introduced the fifth dimension, replacing vision and mission in connecting the other perspectives, which is a human focus. This change reoriented performance measurement towards intellectual capital (Edvinsson 1997). The third type comes from Germany. The initial set of four perspectives is treated as a point of departure towards an increased number of viewpoints, even as many as ten (Friedag and Schmidt 2001). This modification represents the main area of functionality, such as total quality management

or controlling. The last modification of BSCs, very often identifying as a synonym for BSC, is the French method called *tableau de bord* (dashboard). A set of measures offering a quick evaluation of an operations' performance was compared to a dashboard used by pilots since the 1930s in France (Bourguignon et al. 2004). The main difference between BSC and *tableau de bord* derives from their respective purposes. For the French tool, the choice of measures is subjective; they are not so strictly ordered according to earlier defined perspectives, and they are designed to help in organizational learning. On the other hand, BSC measures come from perspectives' types and are pre-defined, more oriented towards accounting. This could be interpreted to reflect the diversity of organizational cultures and leadership styles between France and the United States (Trompenaars and Hampden-Turner 2011).

In general, however, the creation of altered national patterns of the BSC is explained by differences in historical backgrounds, management education, national culture type according to Hofstede's typology, and local philosophical traditions (Bourguignon et al. 2004).

Future Directions

The development of the BSC is still ongoing. According to a review study performed by Z. Hoque (2014), some issues still need to be resolved related to the content of the previous section. One of these directions is to adjust the framework to explain the differences in organizations derived from different countries. For instance, the reason for implementations and the role consultants, among other aspects', could help to understand the BSC modifications which have appeared within certain national contexts. Further development is required regarding the use of the BSC for individual purposes, i.e., focused at personal and not the organizational level. The use of measures for personal development refers to psychology studies on relations between measurement (accounting) and human behavior. A third direction involves the need to analyze the impact

of other institutional research in the use of the BSC, such as dependence on sociocultural norms in a given network. Finally, applying the BSC to the nonprofit sector results in new forms, such as the public value scorecard (Meynhardt et al. 2014; Moore 2003) (► "Public Value"), which has been identified as one promising approach towards measuring public value (Ćwiklicki 2016). The performance measurement practices and changes affecting the public sector especially in emerging economies are pointed out as a promising direction for future research (Hoque 2014). Moreover, some problematic subjects related to BSC's nature are still not fully resolved. This refers to misunderstandings of causality with covariation expressed in strategy maps, factors, and conditions needed for successful implementation and dominated, imposed managerial point of view in BSC's narrative (Nørreklit et al. 2018).

A key test for the BSC will be whether it can serve to solve wicked problems and thereby address the UN Sustainable Development Goals 2030. The BSC methodology could develop into a useful approach to navigate that journey towards creating future sustainable value.

Definition

The balanced scorecard (BSC) is a widely used strategic performance management tool, to support strategy communication, execution, and control. The BSC has a comprehensive scope, based on the inclusion of both financial and nonfinancial perspectives: the customer, internal processes, and learning and growth perspectives. The four perspectives are typically depicted in a strategy map, a visual representation of an organization strategy, linking the strategic objectives in a chain of cause and effects. Strategy maps contribute to communicate strategy, bridge strategic and operational levels, guide employees' behaviors in light of the defined strategy, and support BSC design.

The BSC has been found suitable to support the implementation and control of sustainability strategies. For this purpose, various modifications of the original BSC framework have been developed, in order to include not only economic but also environmental and social issues, leading to the emergence of sustainability balanced scorecards (SBSCs). The modifications to the BSC include various architectures of SBSCs and various ways to integrate sustainability indicators in the SBSCs, making the comprehensive scope of BSCs become even wider and more holistic.

Introduction

The balanced scorecard (BSC) is a strategic performance management tool, with both financial and nonfinancial perspectives, aiming at supporting strategy communication, execution, and control. The BSC, and its associated strategy map depicting organizational strategy across those perspectives, is one of the most widely adopted tools within organizations' management control systems (see ► [“Management Control Systems and Sustainability”](#)). The BSC has a holistic scope by nature, and it has also been adopted within the specific area of sustainability, in order to influence managers' and employees' behaviors and align them with the adopted sustainability strategies, hence promoting the attainment of sustainability objectives. This has led to the development of sustainability balanced scorecards (SBSCs), based on the original BSC but explicitly including environmental, social, or ethical issues (Hansen and Schaltegger 2016).

The ensuing text starts by providing the introductory notions about the BSC. It then discusses the adoption of the BSC to support the management of sustainability strategies in organizations, hence becoming SBSCs. It discusses the various architectures of SBSCs and the various ways sustainability indicators have been integrated into SBSCs. A brief summary closes this text.

The Balanced Scorecard: An Overview

The BSC was developed by Kaplan and Norton (1992), arising from the perception that performance measurement had an excessive financial focus and was neglecting other aspects that were increasingly relevant to the long-term value of organizations. Financial indicators were lagging and too aggregated measures of performance, hence providing limited insights on the drivers of future value. So while Kaplan and Norton (1992) contended that financial performance remained crucial, the financial indicators had to be supplemented by nonfinancial indicators to promote managers' attention to those organizational competencies and results crucial to drive

future financial performance. Importantly, they claimed that no standalone measure could be used as a single performance target and that multiple measures, across different areas of the organization, were required.

Kaplan and Norton (1992) therefore proposed the BSC, initially presented as a performance measurement tool with a balanced approach, adopting not only a financial perspective but also three nonfinancial perspectives: customers; internal processes; and learning and growth. The financial perspective aims at depicting how investors view the organization; it often refers to shareholders, although the scope has also often been enlarged to include other financial investors. The customer perspective aims at capturing the critical factors with regard to customers' perceptions about the value proposition offered by the organization and/or its products/services. The internal processes perspective focuses on the key business processes at which the organization should excel. Finally, the learning and growth perspective identifies the key intangible factors, such as human, information, or organizational capital, which the organization needs to develop in order to improve and create value.

The four perspectives should be integrated into a chain of cause and effects: Developing the key intangibles enables to improve performance in the key internal processes. In turn, this will improve the value perceived by our customers. Improvements in the previous perspectives, in particular in the customer and internal processes perspectives, will ultimately improve the value to the investors. This hierarchical representation of vertical causal relationships, all directly or indirectly contributing to the financial perspective, makes clear that financial performance was considered, in the original BSC, as the ultimate organizational goal. This view was made even clearer, in a more visual way, with the landmark publication Kaplan and Norton (2004a). Strategy maps are a visual representation of the strategy of the organization, in a clear and intuitive way, depicting the chain of cause and effects between the key strategic objectives across the four perspectives. Strategy maps contribute to communicate strategy, bridge strategic and operational levels, guide employees' behaviors in light

of the defined strategy, and support BSC design. As an example, see Kaplan and Norton (2004a, p. 32) for an example of a strategic map, developed for a particular medical equipment company. This holistic integration has also been fostered by the potential cascading of the BSC across the various organizational levels, from the top corporate level to lower levels, such as a strategic business unit, a shared service or some of its functions, a department, or even an individual.

A crucial and sensitive step of the BSC design is to identify (only a few) key performance indicators (KPIs) to measure the attainment of each strategic objective. High-quality KPIs should have certain characteristics. First, KPIs should be technically viable, i.e., have a reasonable degree of reliability. Second, the cost to calculate those KPIs should be reasonable, vis-a-vis their usefulness. Third, the KPIs should include, in a balanced way, both lagging indicators (representing desired results) and leading indicators (representing the drivers that will produce the desired results). Fourth, a KPI should not have dysfunctional effects, meaning that it should be: objective (i.e., clear and unambiguous); complete (i.e., it fully captures all desired attributes, with no need of additional indicators); and reactive (i.e., it clearly conveys the desired action that will influence the indicator and the strategic objective).

Throughout the years, the BSC has experienced continuous development. From an initial emphasis on performance measurement, the linkages with strategy were further developed, and the BSC became a tool for strategic performance management and, later, for strategy execution (Kaplan and Norton 2008).

The literature consistently reports high adoption rates of the BSC. For example, Rigby and Bilodaou (2015), reporting the results of a survey of executives on management trends and techniques, indicate the BSC as the sixth most popular tool, with high satisfaction levels (even though the subsequent survey reported lower usage levels). While the mainstream explanation of the BSC success rests on its suitability to address the functional needs of organizations, Cooper et al. (2017) highlight the importance of global processes of translation and transformation of the tool, as well

as less rational processes based on fads and imitation. Notwithstanding alternative explanations for the BSC success, its wide diffusion, associated with some core characteristics of the BSC, made it a particularly well-suited technique to support the management of sustainability in organizations, becoming a SBSC, as discussed next.

Sustainability and the Balanced Scorecard

The organizational pursuit of sustainability objectives has faced various challenges. Even when organizations develop suitable strategies of sustainability management, it is crucial to develop appropriate systems to measure sustainability performance across the economic, environmental, and social perspectives, so that organizations can control and improve their performance.

The BSC has been considered a suitable framework to support such sustainability measurement and control. The wide scope of the original BSC framework, encompassing not only financial but also nonfinancial perspectives, makes it particularly suitable for this purpose. In addition, bridging the gap between strategy design and its execution, and the strategic and operative levels, is precisely one of the objectives of the BSC (Kaplan and Norton 2008) – and one of the challenges of sustainability management (Bieker 2005).

Indeed, one of the challenges of sustainability management strategy is that this area often fails to be integrated with companies' core processes, both operational processes and control processes. Specifically, the lack of integration with core control processes may mean that sustainability-oriented controls may fail to become embedded in organizational processes and impact organizational decisions and behaviors. Gond et al. (2012) emphasize the need to integrate sustainability within the wider control systems in organizations, in particular within the main management control systems that managers use interactively. Introducing sustainability concerns in a mainstream tool such as the BSC that covers the main areas of performance measurement and

management in so many organizations may be a particularly effective way to support the success of sustainability strategies.

Moreover, the BSC has been typically considered not as a rigid framework to be strictly applied to all settings but as a flexible framework that can be adapted to suit particular contexts. For example, the strategy map referenced above from Kaplan and Norton (2004a, p. 32) adapts the original framework, in particular the internal process perspective, here relabeled “networked processes” to suit the characteristics of the medical equipment company to which it was developed. In particular, public, not-for-profit, and non-governmental organizations, when compared with profit-oriented organizations, have typically a very specific and different nature, vision, mission, and strategies. Very often, these organizations do not have financial objectives as their ultimate goals, and economic concerns come alongside environmental and social ones. This has made many of these organizations to align the BSC with their characteristics, for example, adapting the financial and customers’ perspectives. Therefore, the original BSC framework has been modified in various ways to explicitly include not only economic but also environmental and social issues, in a comprehensive way, as discussed next.

Types of Sustainability Balanced Scorecard Architectures

There are various possible types of modifications to the original BSC, when designing a SBSC, in particular with regard to its architecture – i.e., its overall structure, particularly as depicted in the strategy map, with the various perspectives, strategic objectives, and cause-and-effect chains. Hansen and Schaltegger’s (2016) systematic review of the SBSC literature is a particularly useful study to describe the various architectures and will structure the analysis below. The reader is encouraged to examine this paper to identify the many reviewed articles, since the ensuing text will privilege referencing articles not mentioned in this review.

Prior to presenting the alternative SBSC architectures, Hansen and Schaltegger (2016) identify in the reviewed literature three theoretical standpoints underlying the different designs of SBSCs. First, the instrumental standpoint sees social and environmental issues as a way to improve competitive advantage or organizational efficiency, in line with the idea of making a business case for sustainability; sustainability issues are also seen as a way to improve performance through a strategic management of stakeholders, based on improved relationships, products, or reputation. Second, the social/political standpoint emphasizes how organizations need to address societal expectations and hence be perceived as legitimate and keep their “license to operate”. The third standpoint is the normative/ethical, based on normative stakeholder theory, that aims at total wealth creation, to address organizational responsibilities and a moral duty towards a wide range of stakeholders, rather than simply shareholders.

Hansen and Schaltegger (2016) then identify three main alternative architectures: hierarchical; semi-hierarchical; and nonhierarchical. The first most popular alternative is to keep the strict hierarchical architecture of the original BSC, in which the objectives of the various nonfinancial perspectives ultimately contribute towards financial objectives, in line with the instrumental standpoint of the SBSC promoting competitive advantage or organizational efficiency. See Figge et al.’s (2002) SBSC as an illustration of a strict hierarchical architecture, with all the causal arrows “pointing upwards” (although, as discussed below, adding a “nonmarket” perspective, about child labor, that actually embeds all other perspectives).

The second alternative architecture is a semi-hierarchical SBSC, mostly based on the social/political and normative/ethical standpoint. In this alternative, some approaches relax cause-and-effect chains, in which not all relations among objectives need necessarily to point upwards; this gives a greater prominence to nonfinancial objectives and hence better addressing trade-offs among conflicting interests of distinct stakeholders. This semi-hierarchical alternative architecture also includes approaches which replaced

the financial perspective at the top either with a triple bottom line (see ► [“Triple Bottom Line \(TBL\)”](#)) (Henriques and Richardson 2004)/sustainability perspective or, alternatively, with multiple perspectives, placing the financial perspective alongside environmental and/or social perspectives, at the same hierarchical level.

Finally, the third alternative architecture is the nonhierarchical/network, mostly associated with the normative/ethical standpoint. Rejecting linear cause-and-effect chains, in this nonhierarchical/network architecture, the BSC hierarchy is replaced by a network structure, in which all perspectives are interrelated or are indeed independent, representing a stakeholder scorecard. Conceptual papers were found discussing this architecture, but not empirical ones – an absence credited to the anticipated difficulties due to, for example, a potential loss of focus. Lu et al.’s (2018) proposal of a SBSC for airports illustrates this nonhierarchical/network approach, depicting the interrelationships between all adopted perspectives, including an environmental and a social perspective (but not a customer perspective).

The above examples have already introduced the issue of how to integrate sustainability objectives and indicators in the SBSC. In fact, in addition to the choice of the architecture adopted for SBSCs, there is the issue of how to integrate sustainability objectives and respective indicators, in particular in the highly visual strategy map. This issue is discussed next.

The Integration of Sustainability Objectives in the BSC

Hansen and Schaltegger (2016) identified four alternative ways of integrating sustainability objectives within a BSC, in an increasing level of integration (see also Morioka and Carvalho 2016). The first, and least integrated way, is merely adding a separate sustainability perspective, typically subordinated to the financial perspective. Lu et al.’s (2018) proposal illustrates this “add-on” approach of integration, adding the

sustainability focus apart from other traditional perspectives – even though they consider two separate perspectives (environmental and social), and do not consider the financial perspective as the ultimate goal, given the bidirectional arrows. Hansen and Schaltegger (2016) warn that should the links to the remaining traditional perspectives be weak, this approach has the risk of making sustainability management restricted to the sustainability department, detached from the rest of the organization (see also Gond et al. 2012).

The second way of integration is a (merely) partial integration, which integrates sustainability objectives in one or few perspectives, particularly in the internal processes perspective. The third way is a full integration, integrating sustainability objectives in all four perspectives, which may retain their conventional names or may be relabeled. For example, the customer perspective may become “customers and (external) stakeholders”, “customer and suppliers”, “relational”, or may be complemented by an “employee perspective”. Some SBSCs go beyond the typical (and criticized) internal focus of the BSC and extend it beyond organizational boundaries, changing from internal processes into “network-extended business processes” and from learning and growth to “systemic knowledge and renewal”.

Finally, the fourth, and deepest, way of integration combines the addition of a separate sustainability perspective (as in the first alternative) and the full integration of sustainability objectives within the four traditional perspectives (as in the third alternative). In this approach, the dedicated sustainability perspective is used to include very long-term objectives with scarce or no short-term contribution to financial performance, under labels such as “society perspective”. Figge et al.’s (2002) SBSC, already referenced above, illustrates this deepest way of integration, combining the addition of an encompassing “non-market perspective”, related with child labor, with the inclusion of multiple sustainability-related objectives within the traditional BSC perspectives.

Summary

This text has analyzed how the BSC and the associated strategy map have been used and adapted to support the implementation and control of sustainability strategies. Adding environmental and social concerns to these tools has led to the development of a sustainability balanced scorecard (SBSC). Adaptations include the SBSC architecture and various ways to integrate sustainability objectives and indicators. SBSCs have extended the BSC traditional focus on economic factors by including environmental and social factors. Therefore, the SBSC has the potential to support the success of sustainability strategies, effectively integrating sustainability within core business and control processes and linking sustainability strategies and operational level decisions and behaviors.

Introduction

Issues related to the movement of hazardous wastes across national boundaries have often brought serious concerns to African leaders since the early 1980s, prior to the Basel Convention. This was mainly because Africa was fast becoming a dumpsite for industrialized nations at the time. As a result, there was a resolution in 1988 by the Council of Ministers of the defunct Organization for African Unity (OAU) (now African Union) condemning and confirming that importation of hazardous materials into Africa was a crime against the continent and its people (UNEP 2018a). To support the efforts of governments in developing and implementing efficient regional and national policies for management of hazardous wastes, the Governing Council of the United Nations Environment Program (UNEP) had sanctioned the Cairo Guidelines and Principles for the Environmentally Sound Management of Hazardous Wastes otherwise known as the Cairo Guidelines earlier in June 1987. However, not satisfied by the international community's effort to protect the region, the Council of Ministers of OAU reached a number of resolutions, with Resolution 1153 calling on African states to ban all kinds of hazardous items in accordance to the set guidelines (UNEP 2011; Kummer 1999; UNEP 2018a). A prior recognition of the possibility that the Basel Convention, which was adopted in 1989, would fail to recognize the plight

of the African continent in terms of its environmental pollution, was a major catalyst for resolution 1153. As such, the coming of the Basel Convention and failure to completely address the existing concerns of African nations did not come as a surprise. As a response to the Basel Convention, the Council of Ministers of African Nations again converged at its 49th session and adopted Resolution 1199 (XLIX) on the Global Convention for the Control of Transboundary Movements of Hazardous Wastes, where the position of African continent was made known (UN Commission on Human Rights 1991; UNEP 2018a). One impact of this resolution is the implementation of a complete ban of all kinds of hazardous materials, for which the Basel Convention only mentioned "regulation and control." It was against this backdrop that the Organization of African Unity called on African nations to reach a common ground, to ameliorate the inadequacies perceived within in the Basel Convention, and to ensure their solidarity. As such, none of the African nations who were part of the Organization of African Unity signed the Basel Convention in its first year of existence. Rather, African countries agreed to draft their own guidelines, which are now known as the Bamako Convention (Kummer 1999; UNEP 2018a).

History

The Bamako Convention on the Ban of the Import into Africa and the Control of Transboundary Movement and Management of Hazardous Wastes within Africa, abbreviated simply as "The Bamako Convention," is an extension of the Basel Convention, and an agreement by African countries to officially prevent the importation of all kinds of hazardous waste. The Convention which was originally negotiated by 12 member states of the OAU on 30 January 1991 entered into force on 22 April 1998 (UNEP 2018a, b). A unique feature of the Convention is the fact that it does not leave out any radioactive materials like in the case of the Basel Convention. Thus, it is generally perceived as a more stringent treaty,

though it remains a response to specific sections of the Basel Convention, which encourages regional, bi-, and multilateral agreement for hazardous wastes (UNEP 2018a).

The Bamako convention evolved in reaction to Article 11 of the Basel convention, which encourages bilateral, multilateral, and regional agreements among state parties on hazardous wastes. Of the many lapses within the Basel Convention that gave rise to the Bamako Convention, some were rather critical. First, the Basel Convention relaxed the rules for a few radioactive materials. Second, it was flawed on the ground that no part of the treaty addressed trading hazardous/dangerous wastes to low income countries (UNEP 2019). As such there was continuous shipping of toxic wastes to developing countries (mostly Africa) until the enactment of the Bamako Convention. A popular example is the case of the shipment of several barrels of polychlorinated biphenyls to Nigeria by two Italian firms through the port of Koko in 1987 on the ground that a local farmer would store these wastes for a reward (Adeola 2011). In August 2006, there was another case of waste dumping. This time, it was in Ivory Coast, by a vessel docked at the port of Abidjan. The wastes had been received by a local waste management company and dumped in several parts of the city of Abidjan, having been earlier transported through a ship from Panama by an oil/commodity company based in Singapore. Dumping of these toxic wastes in and around Abidjan caused severe health problems among city dwellers, with several persons hospitalized during the time. In 2008, a lawsuit was filed against the shipping company by a group of concerned citizens, on the ground that the company has refused to take responsibility (UNEP 2018a). However, leaked e-mails exchanged between some traders linked to the firm (obtained about a year after the lawsuit) revealed the possibility of the company knowing the dangers of dumping such materials around human habitations. This situation forced the shipping company into agreeing to pay compensation to the tune of US\$42.4 million, part of which was embezzled as a result of the negligence on the part

of the law firm representing the citizens. In another case in the southern part of Africa, villagers in Chongwe district of Zambia started to excavate tons of beef which the Zambian army had buried after they were imported into Lusaka by an Eastern Bloc country. Some people had started consuming the contaminated beef when the “Times of Zambia,” a leading tabloid published a story that the beef did contain traces of radioactive materials (UNEP 2018a).

The foremost “Conference of the Parties” (COP) to Africa’s Bamako Convention was held between 24 and 26 June, 2013 at the capital city of Mali, where the convention was first signed. Two major resolutions at the meeting include: an agreement to allow the United Nations Environmental Program to act in the capacity of a secretariat for the Convention, and an agreement to push for better cooperation with secretariats of the treaties signed in Basel, Rotterdam, and Stockholm. Other resolutions were the adoption of designated centers of the Basel and Stockholm conventions and the scheduling of the dates for the second COP planned for Abidjan in Cote d’Ivoire (Wahlen 2018). At the second COP meeting held between 30 January and 1 February 2018, and tagged “The Bamako Convention: a platform for a pollution-free Africa,” parties reaffirmed their commitments to the convention and agreed to align efforts of the convention with those of a few chemical management bodies around the world. As listed by UNEP (2018b), the chemical management bodies include:

- The United Nations Environment Assembly’s (UNEA) resolutions on chemicals and pollution.
- The Strategic Approach to International Chemicals Management (SAICM).
- The African Union’s (AU) Agenda 2063.
- The 2030 Agenda for Sustainable Development.

Mission/Objectives/Focus Areas

The main objectives of the Bamako Convention on the Ban on the Import into Africa and the

Control of Transboundary Movement and Management of Hazardous Wastes within Africa according to UNEP and outlined in Eze (2007) and UNEP (2019) include:

- Prohibition of importation of all known hazardous and radioactive wastes/chemicals into member states regardless of the reason for such importation.
- Drastic reduction and control of movements of hazardous wastes within/across the boundaries of member states.
- Prohibition of dumping of wastes and all kinds of incinerated hazardous materials into oceans and inland waters.
- Enforcement of waste disposal in an environmental-friendly manner.
- Promotion of sustainable and green production techniques, so as to attain values even lower than permissible emissions rates.
- Establishment of the precautionary principle.

Structure of Governance/Coverage

The Bamako convention adopts a similar format and approach to that of Basel Convention, except that it exhibits much firmer prohibitions of all hazardous wastes and does not make exceptions to any kind of hazardous wastes. Thus, the Convention has a much wider coverage relative to Basel convention, since it does not only consider radioactive wastes but also any kind of waste that possesses hazardous characteristics including those captured under individual national definitions of hazardous wastes (UNEP 2019). The Bamako Convention mostly investigates the issue of waste disposal and dumping that are not within the Basel Convention, i.e., certain radioactive wastes. This means that any kind of waste that have been restricted in one of the members remains completely restricted by the convention. The convention also provides a comprehensive list of waste streams considered or defined as hazardous wastes and radioactive, which are restricted from dumping, incineration, or importation into the African continent (UNEP 2018a).

As part of the working structure of the Bamako Convention, trading of wastes between parties must be reduced to the barest minimum, so that it can only be conducted with permission from all the states involved from importation to transit and delivery. However, it is important for member states to drastically reduce production of these hazardous substances, and ensure that excess production of such substances is disposed in an environmentally friendly manner (UNEP 2018a).

Though, the first meeting of the conference of parties was convened by the Secretary-General of the OAU as stipulated in Article 15 of the treaty, like many other conventions, the COP is the supreme decision-making body of the Convention. The COP developed its Rules of Procedures including those of other subsidiary bodies which may be established, while it also determines the financial participation of parties (Kaminsky 1992). Though the Convention had much earlier entered into force in 1998, Parties at the first COP which convened in Bamako in June 2013 agreed by Resolution 1/6 UNEA that the Bamako convention Secretariat function should be carried out by the Executive Director of UNEP, subject to approval by the United Nations Environment Assembly (UNEA) (Ashton 2013).

Activities/Major Accomplishments/Contributions

Since entering into force on 22 April 1998, the Bamako Convention has recorded several milestones such as its United Nations registration in March 2000. Furthermore, a document released by the African Union in January 2019 revealed that out of the 55 African nations, 35 had so far signed the agreement to the convention, while 28 countries had ratified it, and 28 have also made deposits. These figures show tremendous progress in the African environmental spheres, following the kind of success already seen with the Basel Convention. While the progress is recorded, some observers have stressed that the Bamako Convention has not lived up to expectations, given that there are suspicions on

the possibility that shipped wastes still find their ways to the shores of Africa (Agbor 2016). While there is no concrete evidence to these allegations, Agbor (2016) further claimed that the slow-paced nature of ratification (while 23 nations had ratified the Convention as of 2010, the figure only increased by 5 nations as of March 2020) seems to breed disagreement of purpose among African nations.

Be that as it may, it is important to stress that in a bid to completely eradicate poverty, and continuous harm imposable to citizens and the environment, African nations have a responsibility to uphold the virtues of the Bamako Convention – an act that will further encourage African power houses of the northern (Algeria and Morocco) and southern parts (South Africa, Botswana, and Namibia) of the continent to join the move. Continuous checks and balances in terms of structure and implementation of the targets of the convention also need to be prioritized, so that there are no back-stabbers in the move to reject making Africa a dumping ground for industrialized nations.

Summary

Prior to the evolvement of the Bamako convention, Africa had become a major destination for global hazardous wastes. Though the Basel Convention was established to protect human health and control the illegal transboundary movement of hazardous wastes, it still could not prevent the continuous landing of radioactive and other hazardous waste at the shores of African countries as shipping companies still exploited loopholes in the treaty. It was this situation that necessitated the birth of the Bamako Convention on the Ban of the Import into Africa and the Control of Transboundary Movement and Management of Hazardous Wastes within Africa with much stringent prohibitions in 1998. Though the Convention has since its evolvement recorded several successes, many African countries are yet to deposit their document of ratification while others have refused to sign up to the Convention.

Definition/Description

Banks are authorized and regulated financial intermediaries that undertake different activities to

meet consumption, savings, investment, and financial risk management needs. Gobat (2012) identifies making loans, creating money, and transmitting money policy as key bank functions. Banks bring savers and borrowers together and, in so doing, reduce the transaction and information costs of mobilizing savings and financing investments. This facilitates economic activity and growth. Modern banks are multi-product firms, with broad distinctions made between commercial banks which combine deposit taking with credit creation and payments services and investment banks. Investment banks help companies to raise funds through the financial markets, offer financial advisory services, and trade financial instruments. Resilient banks that also adopt an inclusive approach to banking have a major role to play in supporting stable economic growth, reducing inequalities in society and advancing several of the Sustainable Development Goals. On the other hand, bank failures and widespread financial instability can be symptomatic of irresponsible business practices in banks and unsustainable ways of value creation that undermine progress toward sustainable development.

Introduction

This entry explores the implications of the functions and strategies of retail commercial banks for achieving the United Nations' Sustainable Development Goals (SDGs). The entry also considers how reforms to the regulatory governance framework for banks contribute to creating an operating environment within which banks could pursue strategies and practices that support economic growth and development, environmental protection, and social welfare.

The traditional financial intermediation theory of banking presents banks as a distinct subset within the group of institutions known as financial intermediaries. In this traditional view, the distinguishing feature of banks is their ability to combine taking deposits and making loans in one institution (Allen and Santomero 2001; Bossone 2001; Werner 2014a).

In an exposition of what makes banks different, Werner (2014a, b) draws attention to the characteristics that enable banks to influence the money supply of a country through credit creation. Bank credit is used to finance consumption, undertake investment for productive purposes and for speculation. Whether as intermediaries or as money creators, banks are essential for financing and facilitating economic activity and economic growth. Hamilton (1781) described banks as the happiest engines that were ever invented for advancing trade and attributed the economic successes of several nations to banks. Hamilton also recognized that banks are subject to abuse and could be harmful. Indeed, the 2008 Global Financial Crisis has been attributed in part to problems with banks' lending and investment activities and weaknesses in banks' corporate governance practices. This entry explores the capacity for banks to both promote and derail the sustainable development agenda. The next section provides an overview of the links that have been made in the academic literature between banks, economic growth, and several of the SDGs. To explore the nexus between sustainable development and responsible business practice in banking, section three examines how the unique features of banks can enhance as well as threaten responsible value creation and governance in the sector. Before concluding, the chapter considers how post-crisis regulatory reforms aim to strengthen the ways in which banks can interact positively with the sustainable development agenda

Banks, Economic Growth, and the SDGs

Banks are the primary financial institutions in most countries despite international differences in financial structure (Levine 1997; Rajan and Zingales 1998, 2001). Most of the academic literature indicates that banks, like financial markets, are important institutions through which financial development can affect economic growth (Levine 2002; Cole et al. 2008; Wolde-Rufael 2009; Beck 2012; Moshirian and Wu 2012; Popov 2018; Tongurai and Vithessonthi 2018; Allen et al.

2018a). Banks can foster growth in several ways. These include mobilizing savings, providing good quality information that will support better decision making for resource allocation purposes, providing external finance, facilitating trade and risk management, and monitoring managers in the businesses they have relationships with to perform a corporate governance role (Levine 1997). Furthermore, as suppliers in loan markets, banks sustain economic growth by making consumer loans which allow people to spend in ways that are not in line with their incomes. In order to repay these loans, people may have to increase the hours they work to repay quicker and reduce borrowing costs (van Griethuysen 2010; Jackson 2009).

By spurring economic growth, it is thought that banks can influence other aspects of economic prosperity, such as reducing poverty (Honohan 2004; Demirgüç-Kunt and Levine 2009). Ultimately it can be deduced that banks may contribute to reducing poverty by making it possible for people to make payments efficiently, manage risks, smooth their consumption, and invest. To date, analysis of the role of financial institutions on alleviating poverty is largely confined to studies of the social impact of microfinance institutions, which are also widely studied as vehicles for promoting financial inclusion (Okpara 2010).

Widening effective access to financial services and inclusive banking are subsumed in several of the SDGs as identified in the SDG Compass developed by the Global Reporting Initiative, the UN Global Compact, and the World Business Council for Sustainable Development (2015). Policy makers make a case for inclusive banking as an enabler of several of the SDGs such as good health and well-being, access to quality education, gender equality, and inclusive growth (Klapper et al. 2016; Demirgüç-Kunt et al. 2017). For sustainable development to occur, banks need to develop useful and affordable products and deliver them through processes that will maximize use and minimize unintended barriers to access (Cámara and Tuesta 2014).

Unlike economic growth and development, the concept of sustainable development involves balancing different goals. The World Commission

on Environment and Development (1987) notes that economic growth is only one aspect of sustainable development and can have negative repercussions on society and the environment. Haapanen and Tapio (2016) highlight that an inordinate focus on an increase in GDP, as a component of sustainable development could disregard actions that support human well-being and protect the environment as well as limit the options for pursuing sustainable development. A recognition of this need for balance between economic, social, and environmental goals underpins why banks are being challenged to engage with other aspects of sustainable development through initiatives such as Banks for a Better World that was launched by SWIFT, a financial cooperative (Stephen and Skinner 2013; Mainelli and Mills 2018). To provide a framework for sustainable banking, a set of six Responsible Banking Principles have been released by the United Nations Environment Programme Finance Initiative (UNEPFI 2019). Formulated in collaboration with the banking industry, these principles outline guidelines for banks in the areas of sustainability impact analysis, target setting and implementation, governance, and accountability. By incorporating such guidelines banks would make more progress toward a sustainable financial system by building a wider repertoire of tools that can reduce and reflect social, environmental, and climate risks (UNEP 2016). Through their Network for the Greening of the Financial System, central bankers and regulators as key players in the management, stability and sustainability of financial systems have come together to urge bankers to integrate climate financial risks into their operations and risk management (NGFS 2019).

Several studies have explored how banks around the world advance and report on the SDGs. Weber (2005) explored banks' motivations for engaging with sustainability and found that European banks had different approaches to sustainability. While some banks adopted sustainability as a strategy or as a value driver, other banks' involvement was in response to clients' requirements or as a public mission. In terms of the reported performance of European banks on the SDGs, Avramopou et al. (2019) found a low

contribution to the SDGs by leading European banks, with SDG4 (quality education), SDG8 (decent work and economic growth), and SDG16 (peace, justice, and strong institutions) being the most well reported. Weber (2012) found that Canadian banks had progressed further than other countries in examining environmental risks when lending. Environmental management, however, is not the main priority of banks in developing countries. Hu and Scholtens (2014) concluded that banks in developing countries have made more progress on social issues when compared to their performance on environmental practices. As banks' sustainability performance extends beyond economic prosperity and social justice, Buranatrakul and Swierczek (2018) explored international banks' response to the climate change challenge and found that North American banks ranked first for developing climate change-related products such as green bond initiatives, loans for renewable energy and clean technology projects, carbon and climate loans, and ecological funds.

With the allocation of funds to productive uses being a core banking activity, other research has investigated the social and environmental impacts of banks' lending and investment activities (Scholtens 2006, 2009; Coulson and O'Sullivan 2014). Studies to date indicate that banks have made considerable progress in integrating their CSR strategies in their lending activities. This progress has been facilitated by two developments. The first initiative, the UNEP Statement by Banks on the Environment and Sustainable Development raised initial awareness of environmental issues in 1991. Since 1991, the statement has been revised and is now incorporated into the Statement of Commitment by Financial Institutions on Sustainable Development (UNEPFI 2011). The second development is the establishment of the Equator Principles in 2003. The ten Equator Principles provide a roadmap for banks to discharge, albeit in a limited way, a primary responsibility to sustainable development through risk analysis and management.

The Equator Principles require banks to apply environmental and social risk analysis in four areas – project finance, project finance advisory

services, project related corporate loans, and bridge loans. Through the application of these principles to lending decisions, banks have a significant impact on environmental and community degradation as well as poverty. The principles also serve as an accountability initiative for banks and have been found to enhance the social accountability of banks (O'Sullivan and O'Dwyer 2015).

The challenge of the SDG funding gap presents an opportunity for banks to simultaneously promote responsible consumption and production patterns in their own activities and indirectly influence these patterns in other businesses through their lending and investment decisions. Meeting the SDGs require considerable redistribution of funds, financial input, and investment. In its 2014 World Development Report, the United Nations Conference on Trade and Development (UNCTAD) estimated that total investment needed to deliver the SDGs in developing countries alone could be about \$ 3.9 trillion a year and that total global investment needs are in the order of \$5 to \$7 trillion a year. To meet the considerable challenges of financing the SDGs, banks do not only need to integrate the SDGs into their operations but national banking sectors need to be reshaped so that domestic commercial banks can work in a complementary way with cooperative banks, development banks, and international banks with a view to creating viable and stable financing frameworks that create shared value. The next section offers a commentary on responsible value creation and governance in banks.

Responsible Value Creation and Bank Stability

At the heart of sustainable development is the notion of shared value creation (Kramer and Porter 2011). Value creation in banks can be approached from the perspective of functional efficiency whereby banks create value through excellence in executing core functions such as origination to gain new customers, intermediation between savers and borrowers, and distribution of products and services through different channels including branches, ATMs, and smartphone

technology. An alternative way of conceptualizing value creation in banks is through the interactions between banks and a complex web of stakeholders. The special problems associated with value creation in banks result in banks having a fiduciary duty to multiple stakeholders such as depositors, creditors, bondholders, the society, and the environment (Macey and O'Hara 2003; De Haan and Vlahu 2016). Detecting and satisfying the expectations of these stakeholders in a way that creates shared value is a clear challenge for banks from strategic to operational level (Formisano et al. 2018).

In the aftermath of the global financial crisis, banks were accused of destroying rather than protecting wealth and stability. According to Chen et al. (2018) in the year following the crisis economic activity declined in half of all the countries in the world, demonstrating the threat banks can pose globally. Irresponsible bank lending which created the US subprime mortgage crisis has been acknowledged by many as a primary cause of the 2008 Global Financial Crisis (Blundell-Wignall 2009; Crotty 2009; Dell Ariccia et al. 2012). Relaxed lending standards which applied less weight to a borrower's ability to repay fuelled a credit boom which preceded the crisis. Banks use of innovative securitization products such as Collateralised Debt Obligations for risk management as well as for investment purposes have also been widely criticized. Responsible financial innovation is an integral part of sustainable value creation and is seen as an important vehicle for creating solutions to economic and social problems (Mainelli and Mills 2018). However, some innovative products and practices, if not developed using consultative and responsible product governance processes, can distort risk-taking, lead to consumer detriment and even contribute to financial exclusion (Armstrong et al. 2012).

Campbell (2018) defines socially irresponsible behavior as occurring when a corporation knowingly takes an action that would harm stakeholders. It also covers instances where an organization becomes aware that it has harmed stakeholders but does not take corrective action. The profit maximization model of governance that commercial banks adopt may contribute to a

short-term value creation perspective in banks. Studies that compared the performance of commercial banks and stakeholder cooperative banks have found that cooperative banks demonstrated more stable performance and resilience in the global financial crisis period. This difference in performance has been attributed to differences in governance models, as member-owned cooperatives do not have to fulfill external shareholders' profit expectations but have a mandate to prioritize economic viability and pursue social as well as economic goals (Birchall and International Labour Office 2013; Becchetti et al. 2016). Building on the work of Fiordelisi and Molyneux (2010) on shareholder value creation, Stankeviciene and Nikonorova (2014) distinguished between shareholder value creation and sustainable value in banks and found that sustainable value creation is associated with positive financial performance banks during periods of financial instability.

The SDG Industry Matrix for Financial Services published in 2015 by KPMG and the UN Global Compact identifies ways in which banks could align their strategies with the SDGs to achieve sustainable value creation. These include sharing anonymized data and risk analysis to inform public policy, developing innovative pricing models that will incentivize sustainable production and using results indicators in their reporting that will measure the implementation of ESG management and the fulfilment of ILO conventions. Similarly, UNEPFI's (2018) Positive Impact framework which specially addresses how banks and other financial institutions could meet the financing gap challenge goes beyond banks' lending and investment to guide banks in sustainable value creation in their product development and ongoing portfolio analysis and monitoring activities. Adoption of these principles and frameworks will not only aid sustainable value creation in banks but also enhance reporting and build the transparency, accountability, and trust required for preservation of function.

Apart from value creation, another important aspect of sustainability is to preserve the functionality and status of institutions and systems. Banks' transparency is one area that has attracted

attention in connection with sustainability, particularly because of the role banks play in financing business activities. The conventional wisdom is that banks are opaque because it is difficult for stakeholders to determine banks' soundness and levels of accountability. This opaqueness can not only make it difficult to determine what progress individual banks are making toward sustainability but also undermine trust and contribute to widespread financial instability (Morgan 2002; Spargoli and Upper 2018).

Bank failure has the potential to undermine the effective functioning of the entire financial system because of the negative externalities that can occur in banking. These externalities are a type of market failure which cause the costs and benefits of banking transactions to spill over to third parties who are not directly involved in these transactions. Consequently, the social costs of a bank's failure exceed the losses that would accrue directly its claimholders, making the bank a potential source of a systemic risk. Bank failure can reduce economic growth through disruption in the payments systems, a loss public confidence in the banking system and through a general reduction in lending (Kupiec and Ramirez 2013).

As a result of externalities, the benefits of good bank performance would accrue privately to shareholders and bank managers who earn bonuses, while the costs of failure would be socialized and disproportionately borne by taxpayers and other stakeholders. This was evident in the 2008 Global Financial Crisis when several banks had to be bailed out and recapitalized by governments using public funds, while bankers continued to receive contractual bonuses. The severe consequences for a range of stakeholders when banks are not managed in a sustainable manner provide a rationale for bank regulation and have prompted recent reforms at national and international levels. For example, in the USA, which was the epicenter of the subprime lending crisis, the Dodd–Frank Wall Street Reform and Consumer Protection Act 2010 include provisions that tighten mortgage lending regulation to ensure that banks are more diligent in evaluating loan affordability. At a global level, the revised Basel Recommendations on Corporate

Governance Principles for Banks is one initiative that aims to strengthen bank stability and rebuild confidence in banks by reinforcing the role of bank boards in oversight, remuneration, and risk governance.

Regulating Banks for Sustainable Development

The regulatory framework is part of the system of governance for banks which contributes to developing the public trust and confidence that is essential for banks to operate successfully. Stronger regulatory governance can play a role in minimizing banking risks and in enhancing banks' accountability while addressing concerns about financial stability, information asymmetry, and unfair competition in banking. A combination of the likelihood of contagion that is inherent in banking and developments in financial globalization, deregulation, and technology can make the consequences of value creation in banks complex, giving them a cross-border dimension. As a result, establishing a global financial architecture for stability becomes an indispensable part regulating banks to support sustainability.

Deposit insurance and government bailouts are the main tools used to provide a safety net that prevents bank runs and panics. The safety net also improves the financial position of depositors and creditors, should a bank failure and crisis occur. These tools are costly to taxpayers and governments. As governments are expected to fund most of the investments required to meet the SDGs, spending on bank bailouts will threaten SDG spending. Spending on bank bailouts is at the expense of spending on other core government commitments such as spending such as health services, systems of social protection and education. Hence bank bailouts have the potential to disrupt progress toward the SDGs. It is widely debated whether deposit insurance and government bailouts can cause moral hazard and increase incentives to take risk because the protection these measures offer is akin to insurance (Diamond and Dybvig 1983; Allen et al. 2015, 2018b; Calomiris and Jaremski 2016). Allen et al. (2015) highlight

that many national governments took steps to mitigate moral hazard after the 2008 global financial crisis through redesigning deposit insurance scheme. National efforts like these are complemented by international initiatives. For example, the Financial Stability Board, an international body set up to identify and monitor financial system vulnerability, now regularly highlights and monitors those large and systemically important banks that would pose a threat to the stability of the global financial system because of their size, complexity, interconnectedness, cross-jurisdictional activity, and the lack of readily available substitutes for their services.

In tandem with these stability measures prudential regulation, including capital requirements, has long been used to limit banks' risk-taking activities and increase banks' resilience by enhancing their ability to absorb loss. The most high-profile international prudential measure is the convergence agreement on capital standards commonly known as the Basel Accord. In the Basel III amendments, the provisions of the Accord were revised to strengthen both the quality and quantity of capital of held by internationally operating banks and to regulate for liquidity as well as credit, market, and operational risks (BIS 2011).

Schwarz (2017) argues that a focus on bank size and moral hazard detracts attention from issues of corporate governance and corporate responsibility in banks which may better explain excessive risk taking. Information asymmetry between banks and their customers and skewed incentives given to staff can result in scenarios where irresponsible conduct on the part of banks could undermine the sustainability of the global banking system. Arguably, regulation that is aimed at improving bank conduct and protecting consumers, who are major bank stakeholders, has attracted the most attention from regulators in recent years because of a proliferation of product mis-selling scandals. By December 2019, the Payment Protection Insurance scandal in the UK had cost banks £38.3 billion in refunds and compensation payments to customers who were mis-sold this insurance with loan and credit products over several years (FCA 2020). Some countries have

set up separate conduct regulatory agencies which have a mandate to protect consumers. These include the Financial Conduct Authority in the UK and the Consumer Financial Protection Bureau in the USA. It has long been recognized that the poor design of bank products, unsuitable advice, and inappropriate sales methods can cause detriment to consumers due to information asymmetry between banks and their customers, the intangible nature of bank products, behavioral biases, and opportunistic behavior on the part of firms (Llewellyn 1995, 1999). Product failure and the failure to create cultures in banks that would promote ethical behavior in sales transactions can undermine trust and confidence, cause misallocation of resources, and result in social costs with widespread losses.

In some countries, structural reforms have been introduced to alter the organizational form of banks through some type of separation or restriction of activity. In the UK, ringfencing rules now legally separate the retail banking services of large banks from the rest of a bank's business. In a similar vein, to contain riskiness, the Volcker Rule which was introduced in the USA in 2013 prohibits banks from owning hedge funds and private equity funds (FDIC 2019). The rule also limits banks from undertaking proprietary trading transactions which is a means for banks to realize direct market gain unlike when they invest on behalf of clients. These reforms will also enhance transparency and accountability which are important principles for sustainability.

Summary

Modern banks meet a range of society's financial and economic needs for investment, savings, money transmission, risk management, and consumption and are indispensable partners in efforts to achieve sustainable development. From a sustainability perspective, banks are unique institutions because of their financing capabilities, the scope for their activities to impact on a web of stakeholders and the threats that market failures such as externalities and information asymmetry

can pose to financial stability and sustainable development. While it is in achieving the goals of economic prosperity such as economic growth and poverty reduction that banks have been most widely studied, more research needs to be conducted into the social and inclusive impacts of banks activities. There is very little academic literature that seeks to investigate empirically the links between banks, banking development, and a range of sustainability indicators and explore links between banking and sustainable development empirically. Furthermore, several initiatives have been established at national and international levels that have the capacity to alter the institutional environments within which banks operate. Another much-needed line of enquiry is to investigate how different institutional environments affect how banks engage with and implement the SDGs.

Base of the Pyramid

Maria Roszkowska-Menkes
Department of Management Theory, SGH
Warsaw School of Economics, Warsaw, Poland

Synonyms

BOP; Bottom of the Pyramid

Description

Base of the Pyramid (also referred to as Bottom of the Pyramid or simply BOP) is a term that refers to the poorest socioeconomic segment that is not well integrated into the formal economy (London and Hart 2011). The term has been popularized by management scholar C.K. Prahalad (2004) (see ► “Pralhad’s “Bottom of the Pyramid””), who argues that the pursuit of profits by private enterprises can alleviate poverty at the base of the economic pyramid. Through the lens of **inclusive capitalism** (Pralhad and Hart 2002), the world’s poorest population is perceived not as victims and recipients of charitable giving but as value-demanding consumers and highly resourceful innovative entrepreneurs (Simanis and Hart 2006). Business ventures at the BOP comprise a broad range of business models designed to target the poorest segments of society (London and Hart 2011). They pursue “a business and development strategy grounded in a synergistic relationship between the generation of economic returns and the solution to social and environmental problems” (London and Hart 2011, p. 4).

Definition of BOP

The origins of the term “bottom of the pyramid” can be traced back to the great depression in the 1930s and president Roosevelt’s radio address about “the forgotten man” at the bottom of the economic pyramid. In its current meaning, the term was introduced by Prahalad and Hart (2002) in their seminal article “The Fortune at the Bottom of the Pyramid” in 2002. The authors described the **world economic pyramid** divided into four tiers. Tier 1 that constitutes the very top of the pyramid comprises 75–100 million affluent consumers – middle- and upper-income people in developed markets and rich elites from the developing countries. The middle of the pyramid, tier 2 and 3, encompasses poor people from the developed countries and middle class from the developing ones. Finally, tier 4, the bottom of the pyramid, refers to the poorest people in the world that constitute the majority (around two-thirds) of global population. Later, some authors proposed to use the term “base” instead of “bottom” because of the negative connotations of the latter (Simanis and Hart 2008).

The literature does not provide precise definition of the bottom tier. Different BOP authors have proposed different per capita income values defining BOP, ranging from \$1500 to \$3000 per annum and \$1 to \$4 per day on purchasing power parity (London and Hart 2011). Thus, as London and Hart (2011) argue, income lines should not be perceived as a rigid definition. Additionally, BOP is not homogenous and can be divided into several segments, such as poverty levels (e.g., extreme, moderate, and relative poverty), urban versus rural locations, or the degree of isolation from mainstream markets (Kolk et al. 2014).

In the light of these inconsistencies, London and Hart (2011) propose to define BOP through its key characteristics:

- The world’s population with the least amount of income
- Not well integrated with the formal capitalist economy
- Living primarily in the informal economy

- Constituting the majority of global population
- Heterogeneous across multiple dimensions

BOP Venture/Business

BOP ventures are defined as revenue-generating enterprises that target the BOP's consumers, sellers, and entrepreneurs. Their objectives include becoming economically self-sustaining and scalable. The two basic types of BOP ventures include those serving BOP consumers and those serving BOP producers.

Despite its size, tier 4 has remained invisible for the corporate sector. Yet, as argued by Prahalad and Hart due to large aggregated buying power of the poor, "low-income markets present a prodigious opportunity" (2002, p. 1) for investment. According to Hart and Christensen (2002), companies engaging at the BOP are not forced to compete against capable competitors over savvy customers but can enjoy competition against non-consumption. Additionally solutions developed in low-income markets are more easily adaptable than models from high-income markets – they can be more easily applied in more places. Originally the concept focused on MNCs as the initiators of BOP businesses. Many of BOP initiatives, however, are led by small, local firms, as well as NGOs and governments (Kolk et al. 2014). BOP businesses span sector and size, often involving cross-sectoral and cross-industry partnerships. Other term to describe BOP venture is inclusive business (see ► [“Inclusive Business”](#) and ► [“Inclusive Innovation”](#)).

Ventures Serving BOP Consumers

Simanis and Duke (2014) identify nine kinds of opportunities for ventures targeted at BOP consumers that often occur simultaneously. Starting with the least and ending with the most complex and resource-consuming, they include:

1. Targeted marketing – messaging strategies focused on illiterate or skeptical consumers that aim at boosting short-term consumption of a product

2. Product redesign – capturing greater market share with product modifications that meet additional needs and increase the overall value proposition
3. Distribution extension – harnessing the existing nontraditional channels that can quickly and easily reach new customers
4. New channel creation – building parallel distribution channel that can penetrate hard-to-reach areas
5. New product development – using present product development capabilities to design an affordable and sustainable product that address an unmet need
6. Conquest a competitor's market – using the company's economies of scale and minor product modifications to outstrip local competitors and capture significant market share where the company has no operations
7. Greenfield market expansion – expansion by tailoring core offering and business model used to serve BOP consumers in one area to meet the needs of similar consumers in a different area
8. New business model development – creating a new business model for company's existing product in order to offer its core functionality to hard-to-reach consumers
9. New market creation – addressing an unmet and latent need among a large population of low-income hard-to-reach consumers

Ventures Serving BOP Producers

Other opportunities relate to building business linkages with BOP producers by engaging local farmers, micro-entrepreneurs, and small business within MNCs' value chains. On the one hand, such business linkages by stimulating job creation, enhancing skills and capacity, and increasing purchasing power contribute to the economic development of the BOP communities. On the other hand, business linkages may translate into competitive advantage, by helping company reach the BOP end consumers more effectively, catalyze innovation, reduce costs, increase flexibility and specialization, and enhance social license to operate. Jenkins et al. (2008) identify three types of opportunities of building business linkages:

1. Buying from BOP partners – sourcing variety of products and services from local suppliers. This form of partnership can help MNCs increase flexibility and reduce costs, as well as increase quality, traceability, and sustainability of supplies contributing to creation of unique product offer and enhancing company's legitimacy.
2. Distributing through BOP partners – partnering with local small and microenterprises to reach target consumers at the BOP. Distribution partnerships allow to overcome challenges related with low sales volumes and/or price points and poor infrastructure that make usage of traditional distribution methods (e.g., big trucks) either cost-ineffective or impossible. Additionally local distributors play a crucial role in marketing of MNCs' products, as they help in building consumer trust and awareness.
3. Selling to BOP partners – delivering products and services, including financial services, communications and information technology, or production equipment, that contribute to the increase of productivity of small and microenterprises at the BOP. Creation of this kind of business linkages often requires product and process adaptation that drives creativity and innovation in MNCs.

Challenges

In order to tap the opportunities presented by the BOP, companies first need to face set of challenges. Tier 4 consumers live mostly in poorly communicated rural areas or urban slums; they are poorly educated and cannot afford good quality products and services sold in developed countries. They live in high-cost microeconomic systems dominated by local monopolies and often operate in the underground economy (Prahalad and Hart 2002). Profits at the BOP cannot be driven by traditional high margins but rather by volume and capital efficiency. Yet, as some (Simanis and Hart 2006) argue, the cost structure and material intensity of MNCs' current business models preclude the introduction of low-cost strategies.

Prahalad and Hart (2002) underline the need to develop commercial infrastructure enabling effective business operations at the BOP (see

► “Prahalad's “Bottom of the Pyramid””). This encompasses creating buying power of the poor by providing access to credit and opportunity for income generation; developing distribution systems and communication links; shaping aspirations; and tailoring solutions to unique needs and problems of local communities. The latter includes addressing severe environmental problems in developing countries as well as completely different set of institutional and cultural factors that the BOP markets are characterized by.

Addressing challenges at the BOP requires innovation in technology, business models, and management processes, as well as wide multilateral partnerships with financial institutions, other companies, local governments, NGOs, and communities (London and Hart 2011; Prahalad 2011; Prahalad and Hart 2002; Simanis and Hart 2006).

Evolution of the BOP Business Concept

BOP 1.0 (See ► “Prahalad's “Bottom of the Pyramid””)

Early literature on BOP as well as the majority of corporate initiatives in this area followed one-direction approach of selling products to the masses of underserved consumers (London and Hart 2011). First generation of BOP (BOP 1.0) strategies has been centered on four dimensions: 1. affordability, building affordable products and services that match cash flows of BOP customers; 2. acceptability, creating culturally acceptable solutions adapted to the unique needs of customers and distributors at the BOP; 3. availability, ensuring availability of products and services for the hard-to-reach customers; and 4. awareness, raising awareness through unconventional advertising media (Anderson and Markides 2007).

However, as some authors (Karnani 2006; van der Klein et al. 2012) argue, the extent to which such activities served the poor remained questionable. The poverty alleviation strategies outlined in BOP 1.0 literature were premised on the consumption-based economic growth theories from the 1950s. Companies have viewed poverty primarily as a question of basic needs such as hygiene, access to drinking water, or electricity

needs (Simanis et al. 2008). Although BOP 1.0 strategies often involved the poor as producers and included income generation component, majority of them were centered on simple income expansion that leads merely to increase in consumption and did not include any forms of empowerment or participation. Simanis et al. (2008) argue that the basic needs thinking is often viewed as a paternalism and cultural imperialism devaluating the cultures and traditions of the poor. As such it may face resistance from local NGOs, governments, and communities, who perceive corporations' engagement at the BOP merely as a smart strategy for selling to the poor. Additionally, in the BOP 1.0 literature, the bottom of the economic ladder has been viewed as a one homogenous market, while as Simanis et al. (2008) note, it is not a market at all but a demographic classification.

BOP 2.0 and the BOP Protocol

In the later stream of BOP, the research focus has shifted from selling to the poor toward co-creating new markets, business models, and technology solutions (London and Hart 2011). Some authors (London and Hart 2011; Simanis et al. 2008) call to perceive local communities not only as consumers and producers but as co-inventors or business partners involved in a process of a deep dialogue and mutual learning. Second generation of BOP strategies (BOP 2.0) has been based on a co-venturing approach that marries “the capabilities and knowledge of corporations with those of the communities and embed the business within the existing socio-cultural institutions” (Simanis et al. 2008, p. 64). MNC takes the lead in the process, but its strength is reinforced by local NGOs, public authorities, as well as smaller, more flexible, innovative, international, and local companies (van der Klein et al. 2012). The role of MNC in poverty alleviation alters “from that of a “development doctor,” who diagnoses the poor’s problem and prescribes the solution, to that of “enterprise facilitator,” who assists the poor in acting on their self-defined aspirations” (Simanis and Hart 2006, p. 43). As this requires an entirely new strategic process and corporate capability,

Simanis and Hart (2008) propose an approach called the Base of the Pyramid Protocol.

The core principles of the BOP Protocol are “mutual value” and “co-creation.” According to the first, each stage of the process must create value for all partners. The latter emphasizes the partner-based relationships with BOP communities. Co-creation not only catalyzes creativity but also ensures cultural fit and environmental sustainability of the business model (Simanis and Hart 2008). The protocol represents a shift from Structural Innovation Paradigm (SIP) toward Embedded Innovation Paradigm (EIP) (Simanis and Hart 2011). While SIP focuses on satisfying consumer needs better, faster, and cheaper than competitors through structural changes to a company’s business system, EIP’s aim is to re-embed consumers and producers back into the society by building cooperative communities. Table 1 presents main differences between the two paradigms.

While SIP is driven by the belief in the unmet needs in the society, EIP focuses on a latent potential within diverse economies. Within SIP, companies compete for customers on the basis of consumption-based value, i.e., value (understood as ratio of quality to price) contained within products and services. EIP, in contrast, aims at creation of relationship-based values – values residing in the community relationships, like fraternity, sense of belonging, excellence, growth, and learning. Finally, within SIP, companies have transactional approach toward stakeholder engagement. External stakeholders are viewed as a source of knowledge, resources, and capabilities that a company needs to assess in order to satisfy consumer needs. The shift toward EIP induces transformational

Base of the Pyramid, Table 1 Comparison of Structural Innovation Paradigm and Embedded Innovation Paradigm

	SIP	EIP
Focus	Latent needs	Latent potential
Value created	Consumption-based	Relationship-based
Stakeholder engagement	Transactional	Transformational

Source: own elaboration

stakeholder engagement that aims at the creation of new stakeholder behavior, habits, and identities necessary for realizing a new enterprise.

Managers involved in BOP initiatives based on the protocol are guided by the following code of conduct (Simanis et al. 2008):

- Creation of businesses that increase earning power, remove constraints, and build potential of local communities
- Equal share in wealth generated by the business
- Use of sustainable technologies
- Promotion of the development of affected communities
- Performance of the business measured in terms of “triple bottom line”
- Addressing negative impacts of the business model
- Sharing the best practices with local partners
- Transparent communication and dialogue with stakeholders
- Commitment to increase community value regardless of the business outcome

In the absence of an existing product market that can be researched, the BOP Protocol uses action-learning techniques for defining business concept and the new value proposition in a low-risk manner. Action learning helps building locally embedded businesses and committed local markets. The protocol consists of three interdependent phases of activity that take approximately 3 years to complete. Phase I: Opening Up includes a company immersion in the community using home stays, recruitment of community team, and business concept co-creation workshops. During the Phase II: Building the Ecosystem project team comprising company and community representatives is formalized. Its aim is to create an initial brand and product/service prototype through intensive action learning that engages the wider community. In the last phase, Phase III: Enterprise Creation, the project team creates a full working business model using small-scale tests and continued action learning within even broader community segment. At this

stage, the aim is also to build local management capacity so that, in the future, community team is able to manage and grow the business independently (Simanis and Hart 2011).

As reported by Kolk et al. (2014), still the vast majority of examples of BOP initiatives provided in the literature engaged the locals as recipients, rather than as co-inventors. Most of BOP ventures reported in the literature view the poor as consumers of existing or adapted products and do not involve co-invention. Examples of initiatives, where the degree of adaptation is significant leading to radical business model innovation, are still rare.

Back to Business Fundamentals

The BOP Protocol methodology was field tested by three ventures: an initial pilot in Kenya by SC Johnson; the DuPont subsidiary, Solae, in India; and a US-based effort on healthcare provision in low-income communities. However, all three tests ended in failure. Some authors argue that the reason for these failures was that the ventures were focused rather on philanthropic efforts and not on profits and growth (Simanis 2012; Simanis and Milstein 2012). The goal of the test projects to develop new business model for BOP markets was nebulous and not linked to any specific business objectives. The original concept of BOP framed through a business lens has undergone a complete inversion with for-profit corporations “rapidly falling from its ranks, and filling their place in an expanding number of government and non-profit organizations” (Simanis and Milstein 2012, p. 82).

Simanis and Duke (2014) argue that BOP ventures in order to be socially beneficial and sustainable over the long term need to focus on profits and make investment decisions basing on their core capabilities and not on social commitment. Simanis and Milstein (2012) propose four changes to management practice at the BOP. First, managers need to drop the term “Bottom of the Pyramid,” which has poverty alleviation focus, and shift, instead, to using the term “Developing and Emerging (D&E) Markets.” According to the authors, using “BOP” term is a risky internal and external communication strategy.

Internally it aligns the venture with corporate philanthropy and not core business. Externally it creates risks for business-focused ventures to be labeled “a poverty wash” (Simanis and Milstein 2012, p. 86). Second, while defining business case for D&E investment, managers should stop focusing on ambitious goals and possibilities for disrupting the entire industry but rather identify concrete and tightly bounded business opportunities that match the already defined objectives and investment parameters of a specific unit in the company. Third, at the field level, before engaging community and co-designing a product, managers need to first identify key business economic drivers, including fixed cost base, wages, price points, gross margins, penetration rates, and customer sales loads. These drivers serve as viability screening criteria for different ideas occurring during product and business model brainstorming sessions. Finally, to evaluate D&E projects, managers should shift from external impact assessment to key business metrics of performance.

Summary

BOP is a management concept introduced by Prahalad and Hart (2002). The idea lying at the heart of it is that the low-income countries represent multitrillion-dollar market full of unmet needs and untapped business opportunities. While developed markets are increasingly saturated and provide limited future growth opportunities, the underserved needs at the BOP offer massive growth potential for multinational corporations (MNCs) (Simanis and Hart 2006).

The concept has evolved in three stages, from a one-directional model focused on selling to the poor (BOP 1.0), through socially-committed ventures based on co-creation partnerships (BOP 2.0), toward strictly business-focused ventures in developing and emerging markets.

Synonyms

[Basel convention](#)

Definition/Description

The Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal was adopted on 22 March 1989 by the Conference of Plenipotentiaries in Basel, Switzerland. It entered into force on 5 May 1992. It is signed by 187 countries (Basel Convention 2019a).

The main objective of the Basel Convention is to “protect human health and the environment against the adverse effects of hazardous wastes” (UN 1992). It is the first international legal instrument that provides legally binding rules for international hazardous waste trade and management.

The scope of application of the Convention covers wastes defined as “hazardous wastes” based on their origin and composition, as well as household waste and incinerator ash waste (UN 1992). The principle aims of the Convention are the reduction of hazardous waste generation, reduction of transboundary hazardous waste movement, and regulation of the permitted transboundary hazardous waste movement (Kummer Peiry 2013).

In addition to the Convention there are two supplementary documents that are attached to it, and that parties of the Convention can be a part of. The first is the Basel Protocol on Liability and Compensation, which was adopted on 10 December 1999 (Basel Convention 2019b) after the Fifth Conference of Parties (COP-5) that took place in Basel, Switzerland (Basel Convention 2020c). The second is the Amendment to the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal, also known as the Ban Amendment, adopted in 1995, signed by 97 countries (Basel Convention 2019c) in Geneva on 22 September 1995, and entered into force on 5 December 2019. The Convention’s main purpose is to promote environmentally sound waste management (UN 1992).

The last amendment of the Basel Convention is to enter into force in 2021 and is concerning plastic wastes (Basel Convention 2020b). The Plastic Wastes Amendments were adopted at the 14th COP of the Basel Convention in 2019.

The Basel Negotiation Process

The issue of international transport of hazardous wastes became a topic of discussion in the 1980s with its culmination being a case of transportation and storage of toxic waste in Nigeria where a number of people were injured and toxic waste was spilled into the environment (Evans 1996). The debate over illegal transboundary traffic in toxic waste reached its peak in 1988 when media reports on incidents involving illegal dumping of toxic waste from industrialized nations in developing countries were spiking up international and national society (Kummer Peiry 2010). The issue became internationally significant and was taken up by different institutions – governments, inter-governmental organizations, and non-governmental organizations (Kummer Peiry 2010).

Based on a joint proposal by Switzerland and Hungary, in June 1987, the Governing Council of UNEP mandated the Executive Director to convene a working group for elaborating a global

convention on the control of transboundary movements of hazardous wastes. The negotiation process was endorsed by the UN General Assembly (GA) (Kummer Peiry 2010).

The Basel Convention was signed in the end of the Conference of Plenipotentiaries on the Global Convention on the Control of Transboundary Movements of Hazardous Wastes, that took place from 20 to 22 March 1989 in Basel, and that was attended by 116 representatives of states (Basel Convention 2019a). The conference was the final event of the series of negotiations that took place between 1987 and 1989 in relation to developing a mechanism for environmental management of international import and export of hazardous waste (Kummer Peiry 2013). The Basel Convention was designed and adopted as a measure for mitigating the negative effects of the so-called “toxic trade.”

The Basel Convention was closed for signature on 22 March 1990. It entered into force on 5 May 1992 (Kummer Peiry 2010). As of September 2019, there are 187 parties to the Basel Convention (Basel Convention 2019d).

Key Provisions of the Basel Convention

The Basel Convention is a legally binding international treaty, and its provisions are obligatory for countries that have signed and ratified the document. Each country has the right to make declarations or reserves on certain provisions, and some countries have made such. A formal objection has been made by Italy, which stated that “no provision of this Convention should be interpreted as restricting navigational rights recognized by international law. Consequently, a State party is not obliged to notify any other State or obtain authorization from it for simple passage through the territorial sea or the exercise of freedom of navigation in the exclusive economic zone by a vessel showing its flag and carrying a cargo of hazardous wastes” (Basel Convention 2020d).

The Convention provides a regulatory system for management of waste import and export. It is founded on the concept of prior informed consent, so it establishes the rule for countries to agree explicitly (written consent) to an international waste trade and management procedure before a transfer is made (UN 1992).

The scope of the Convention covers a range of waste types defined as “hazardous wastes,” which are defined as such based on their origin or composition, and their characteristics, and are separated from “other wastes,” which are not meeting the Convention’s criteria for “hazardous wastes” (UN 1992).

The principal aims of the Convention, as author Katharina Kummer sums up, are as follows:

- The reduction of the generation of hazardous waste and promotion of environmentally sound management of hazardous waste in every place of disposal.
- Restriction of transboundary movements of hazardous wastes except where it is perceived to be in accordance with the principles of environmentally sound management.
- Foundation of the regulatory system that is to be applied to cases where transboundary movements of hazardous wastes are permissible (Kummer 1998).

The Convention provides general provisions requiring states to observe the fundamental principles of environmentally sound waste management (Article 4) (UN 1992).

It establishes the borders where hazardous waste cannot be exported to (UN 1992). It also regulates matters of action in the event of illegal transport and import of hazardous waste. It attributes responsibility to the states involved.

The Convention provides the foundations of management of international waste transfer. It establishes the minimum of regulation that is to be kept by countries. Following international legal principles, all bilateral or multilateral agreements on hazardous waste management with other

parties or with non-parties are encouraged provided that they are “no less environmentally sound” than the Convention’s provisions (Article 11) (UN 1992).

Non-trade issues for cooperation between parties are handled as well. Ranging from information exchange to technical assistance, the Convention provides legal foundations for the development of such a system (Article 10 and 13) (UN 1992). The establishment of regional centers for training and technology transfer is provided as well. According to the official webpage of the Convention, 14 centers have been established (Basel Convention 2020a).

The Convention emphasizes on the need for assistance (including technical assistance) to developing nations (UN 1992). The idea behind this is that most developing countries do not have the technologies to manage hazardous waste properly, but they are receiving a large proportion of that waste, despite them more often being the importers of waste in global “toxic trade.”

The Secretariat of the Convention, which is the main administrative structure that supports the implementation of the Convention, facilitates this cooperation (UN 1992). It is situated in Geneva, Switzerland. The Executive Secretary of the Secretariat is Katharina Kummer Peiry, who has occupied this position since 2011 (Basel Convention 2020e).

Global Governance of Toxic Trade

In the early 2000s political discussion over the 1995 Ban Amendment of the Convention, which banned all waste exports from OECD to non-OECD countries, was essential to the governance of “toxic trade” (Kummer Peiry 2013). After a protracted series of efforts by some developed countries to weaken or undermine the Ban Amendment including a bid to interpret the Convention to delay entry into force, at the Tenth Conference of the Parties in 2009 it was decided that the Ban Amendment would enter into force with 3/4 of the Parties present and voting at the

time of its adoption in 1995 (BAN and IPEN 2020). In 2019 with St. Kitts and Nevis and Croatia being the final two ratifying countries to complete the required number for entry into force of the amendment, the Ban Amendment entered into force on 5 December (BAN and IPEN 2020).

The Basel Convention has been considered as one of the more important legal instruments that promote the world polity of international problem-solving and governance (Gareau and Lucier 2018). Despite being a traditional international treaty, signed and implemented by nation states, the provisions of the document actually have a wide spectrum of stakeholders including nongovernmental organizations, industry actors, and the general public.

Despite that environmental nongovernmental organizations (NGOs) have been advocating the complete prohibition of shipments of all waste materials from North to South (Evans 1996), the shift in perception of waste as raw material resources made them more willing to conditionally acknowledge that under proper management waste trade can be environmentally and economically sound and can create opportunities for “green” business (Kummer Peiry 2013). In recent years emerging economies became noticed as new players with an interest in the potential of green business opportunities and jobs stemming from waste raw material production and management (Kummer Peiry 2013).

The concept of environmentally sound management that the Convention provides thus became a key factor for global governance of this type of international trade. The Basel Convention requires that transboundary shipments of hazardous wastes be sent only to facilities with environmentally sound management, with “environmentally sound management” being defined in general terms (Alter 2000, p. 115). Specific responsibilities on the operator of a facility are placed, and environmentally sound management practices are required to comply not only with general international regulation but with local environmental regulations and standards as well (Alter 2000).

In recent years the Basel Convention has become a significant instrument of international law to regulate trade of ever more important wastes such as plastic wastes (Basel Convention 2020b), and e-wastes (Khan 2016). With the adoption of the Plastic Wastes Amendments and the entry into force of the Ban Amendment, the plastic and e-waste regulation on an international level is hoped to provide efficient ways for combatting illegal international trade of such materials. With watchdog environmental organizations such as the Basel Action Network (BAN) publishing investigations on both how e-waste is traded among nations (which they detected is sometimes illegal) and the damaging effects of e-waste to environment and people (BAN 2019), the Ban and Plastic Waste Amendments' effective international implementation becomes of crucial importance. The amendment that regulates the transboundary shipments of plastic waste entered into force on 1 January 2021 (Synergies 2021b).

Efforts to create a global governance framework for waste management take form of cooperation between actions of the Basel Convention, Stockholm Convention on Persistent Organic Pollutants, and the Rotterdam Convention on Pesticides and Industrial Chemicals (Synergies 2021a).

Despite efforts to provide efficient forefront regulation to international trade of waste, there still has been some criticism toward the governance regime that the Basel Convention establishes. Opinions of criticism have included the idea that the Convention is impeding international trade and creating national autarky in relation to waste management. From the viewpoint of free trade supporters in international economics, this is considered an obstacle for efficiency and essentially leads to higher costs for waste management on both the national and global level (Evans 1996).

Introduction

The Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal (hereinafter referred to as “the Basel Convention”) is a child of necessity that came into being after series of dialogue between the industrialized nations and the third world countries on the sound management of hazardous wastes (Andrews 2009). Prior to the birth of the Convention, especially in the early 1980s,

international trade in hazardous wastes had thrived tremendously as most developed countries shipped their toxic wastes to less developed countries for disposal. Importation of toxic wastes from abroad became a big international business and indeed flourished as many of the impoverished developing countries especially in Africa were desperate for foreign currency (Krueger 2001; Andrews 2009). Poor public environmental awareness in the developing countries had made such cross-border transport of hazardous wastes easy. Thus, multiple stories of the misadventure of “toxic wastes trade” such as the Koko village and Khian Sea waste disposal incidents seized front page news across the world. This was the basis upon which the Basel Convention was negotiated to combat international shipment of hazardous wastes (Andrews 2009).

Waste is adjudged to be hazardous if it exhibits some of the following characteristics: explosive, corrosive, flammable, oxidizing, poisonous, infectious, and toxic, or contain one or more of the following constituents: arsenic, cadmium, strong acids and bases, cyanide, lead, mercury, and persistent organic pollutants, etc. Notable sources of hazardous wastes include but not limited to clinical waste, radioactive waste, metals, and plastics. Other sources are wastes from the production of drugs, medicine, organic solvent, ink, dyes, paint, adhesive, glue, and wood preservatives (Okaru 1993; UNEP 1989). The Basel Convention however excluded radioactive wastes, incinerator ash, infectious waste, as well as poisonous fertilizer like DDT from the broad definition of hazardous waste. Improper handling and disposal of these wastes has the potential of causing immediate or long-term impacts on human health and the environment, usually through leakages of toxins into groundwater, soil, waterways, and the atmosphere (Andrews 2009; Choksi 2001).

History

In the 1970s and 1980s, there was a drastic increase in environmental awareness and the

understanding of the harmful effects of hazardous wastes on human health and the environment. Thus, the developed countries had begun to enact stringent regulations on the disposal of hazardous waste leading to the escalation of treatment and disposal cost. In an attempt to seek cheaper alternative elsewhere and to bank on the nonexistence of environmental awareness and enforcement mechanisms mostly in the developing countries, the industrialized countries had turned to Africa and Eastern Europe for the dumping of waste that were known to have negative impacts on human health and the environment (Hackett 1990). Mindful of the growing threat posed by the continuous generation and transboundary movement of hazardous waste, the international community launched treaty negotiations under the authority of the United Nations Environmental Program, which eventually led to the adoption of the Basel Convention on the Control of Transboundary Movement of Hazardous Waste and Their Disposal in March 1989 (Peiry 2010; Andrews 2009). High profile cases of hazardous waste dumping in developing countries include: the storage of 8000 improperly marked hazardous waste in Koko, Nigeria, that eventually leaked to the environment as well as exportation of toxic wastes to communities in Zimbabwe, Congo, Liberia, Gabon among other nations without the consent of the host nations (Andrews 2009; Okaru 1993).

Originally, the conception of Basel Convention was to find a meeting point for the conflicting views of nations which had supported the implementation of a complete ban of transboundary trade in hazardous wastes and those which hold the “no ban” view. Here, many developing nations have contended and shared the view with European Union (EU) and alliance of Environmental NGOs that banning trade in hazardous wastes will best ensure that industrial nations deal with their wastes locally than shipping them to developing nations which often lack the capacity to manage them (Hackett 1990). On the contrary, many of the non-EU industrialized nations aligned with a few but important developing nation including India and Pakistan to oppose the ban arguing that a total ban will not serve the best interest of the global

environmental and economic development. Thus, in reconciling the opposing views, the Convention chose to regulate the trade in hazardous waste rather than implementing a total ban (Andrews 2009; Peiry 2013).

Issues of regulation of hazardous wastes have been on top of the global environmental agenda since the early 1980s, as one of the three issues of prime concern identified and adopted by the Governing Council of the United Nations Environment Programme (UNEP) on November 6, 1981, in the Montevideo Program on Environmental Law. However, the Basel Convention was adopted on March 22, 1989, and came into force on May 5, 1992, following negotiations that lasted between 1987 and 1989. There are 187 parties to the Basel Convention (UNEP/SBC 2002).

Objectives and Key Provisions of the Convention

The overarching objective of the Basel Convention is hinged on the need to protect human health and the environment and provide solutions to most of the pressing issues associated with the transboundary movement of hazardous waste (Andrews 2009). This objective is built on three targets: (i) minimization of the volume of hazardous wastes generated; (ii) limitation of the amount of cross-border movement of toxic wastes; and (iii) promotion of Environmentally Sound Management (ESM) of hazardous waste (Peiry 2010).

To particularly achieve these targets, several prohibitions are designed to ensure that hazardous wastes are not exported to Antarctica, a state not party to the Convention or a nation in which importation of hazardous waste has been banned. Article 4(5), for example, totally prohibits trade in hazardous wastes between the party and nonparty States to the Convention, while Article 4 reiterates the right of every party not to allow the importation of wastes, whether toxic or not, into its territory. However, provisions were made to allow parties to go into bilateral and multilateral agreement on hazardous waste management, provided

that such agreements are in tune with the Environmental Sound Management principles of the Convention. This provision is entrenched in Article 4(9) where the Convention established three conditions under which transboundary movement of hazardous wastes and other wastes are permitted. Furthermore, where such transboundary trade wastes must take place, the procedure of Prior Informed Consent (PIC) must be followed under the principle of ESM. The PIC as implied in Article 6 requires that the waste generator (i.e., the organization or state of origin) must notify in writing, the relevant authority in the waste receiving states well beforehand, informing them of the nature and characteristics of the waste to be shipped and all parties involved (Andrews 2009; UNEP 1989).

Basel Ban Amendment

Following the adoption of the Basel Convention, the underlying factor that led to its birth came to the fore again. This time some countries of the global south once again aligned with some environmental NGOs and argued that the Convention had not effectively regulated the transboundary trade of wastes (Goldberg et al. 2019). Though the Convention prohibits the shipment of hazardous wastes in Antarctica, it only requires the “Prior Informed Consent” for export to other destinations in the world. Traders in wastes have consistently exploited the recycling option to justify shipment of toxic wastes to developing countries. This was the premise upon which the Bamako Convention was adopted. Thus, the coalition calls for a complete ban of shipment of hazardous wastes to the developing countries (Andrews 2009; Krueger 2001).

At the Conference of Parties (COP) of the Convention in 1995, several EU countries joined the coalition of the developing countries and environmental NGOs and led the adoption of an amendment to the Convention, otherwise known as “the Basel Ban Amendment.” However, the amendment cannot become effective except it is ratified by three-fourths of the parties to the

Convention (UNEP 2019). Croatia submitted her document of ratification on September 6, 2019, and became the 97th State to do so and on December 5, 2019 (90 day after the receipt of instrument of ratification by at least three-fourths of the parties), in accordance with Article 17(5) of the Convention, an amendment to the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal entered into force. The Basel Ban Amendment prohibits the movement of hazardous wastes for any reason from a list of industrialized countries (mostly OECD countries) to developing countries (Goldberg et al. 2019; UNEP 1989).

Summary

The Basel Convention is the only universal treaty on the management of waste. The Convention which was negotiated in 1989 and entered into force in 1992 was became necessary following growing reports of illegal international trade in hazardous wastes resulting in shipments mainly from industrialized countries to the developing ones. Thus, the primary goal of the Basel Convention was to protect human health and environment through the regulation of transboundary movement of toxic wastes. However, after the Convention had entered into force, some developing countries argued that, despite the adoption of the Convention, transboundary shipment of wastes still flourished since traders in wastes only require the “Prior Informed Consent” to ship their wastes across borders. Backed by many countries from the European Union and some NGOs, these countries therefore negotiated for a total prohibition of shipment of hazardous wastes to the developing countries, a move that led to an amendment to the Basel Convention termed “the Basel Ban Amendment” in 1995.

Corporate governance principles

Definition

The Basel Recommendations on Corporate Governance Principles for Banks are a set of high-level guidelines that provide standards on how banks should approach establishing sound and transparent decision making and risk management structures and processes (BIS 2015). Bank governance standards aim to enhance bank stability and the confidence that shareholders and stakeholders, such as creditors have in banks (Becht et al. 2011). The Basel Recommendations on Corporate Governance principles for Banks are published by the Basel Committee for Banking Supervision (BCBS) that is headquartered at the Bank for International Settlements in Basel, Switzerland. As banks play a key role in channeling funds to productive investments and in facilitating payments, good governance in banks is instrumental in promoting sustainable development and in preserving natural systems and social stability.

Introduction

Following the 2008 global financial crisis governance weaknesses in banks, especially in the case of the largest banks, were widely cited as

fundamental flaws in financial systems that threatened sustainable growth (Walker 2009; Kirkpatrick 2009). Subsequently, national governments and the international community, including the Basel Committee on Banking Supervision (BCBS), the Organisation for Economic Corporation and Development (OECD), and the Financial Stability Board (FSB), have taken steps to foster robust standards in corporate governance. The 2015 Basel Recommendations on Corporate Governance (henceforth Basel Recommendations) are part of the broader international efforts to promote prudent management and mutually beneficial engagement with stakeholders that will support long term success and stability in banking. Revised Principles of Corporate Governance issued by the OECD are another part of these efforts (OECD 2015). The International Monetary Fund identified a weak global financial architecture as another failure that, together with the corporate governance shortcomings of banks, contributed to the widespread instability that accompanied the 2008 global financial crisis (IMF 2009). The term global financial architecture refers to the network of international financial institutions (IFIs), policy initiatives and rules that facilitate financial stability and the smooth flow of funds at a transnational level. The Basel Recommendations join other efforts to provide a more robust global financial architecture that will maintain financial sustainability, support economic growth, and foster stable and inclusive societies.

Engagement with the sustainable development agenda focuses the attention of businesses on stakeholders and relational concerns (Steuer et al. 2005; Leal Filho and Brandli 2016). This focus puts both relationships and transactions at the heart of business decisions that focus on long-term success. Corporate governance involves a set of relationships between a company's management, its board, its shareholders, and other stakeholders (OECD 1999). This view of corporate governance that emphasizes relationships has been adopted by the BCBS in the corporate governance principles that it provided to banks as recommendations.

The principles that the BCBS recommends are not legally binding on any national government. They are issued by the BCBS in line with the forum's mandate to enhance financial stability by

strengthening the regulation, supervision, and practices of banks. The BCBS' approach of using principles to provide guidelines that will influence the behavior of banks has many advantages (Black et al. 2007; Ford 2010). A principles-based approach allows banking regulators to set the high-level goals and outcomes that banks are to achieve. Furthermore, this approach gives the banking industry itself the responsibility of specifying the processes and details that will achieve the outcomes that regulators require. The flexibility that principles afford to banks can allow each bank to make decisions that are in line with its characteristics. Banks vary in terms of size, risk profile, and complexity and these differences give rise to different governance requirements. This flexibility is often presented as one of the advantages of principles-based regulation. Alexander (2009) points out that principles shift the focus of regulators and supervisors away from the strict application of prescriptive rules to allow for a closer look at the effectiveness of compliance processes. As with all regulatory approaches, the use of principles has limitations. By focusing on outcomes instead of prescribing rules, a principles-based approach can lead to a lack of certainty. Another concern about principles-based regulation is that it may even encourage regulatory creep – a situation where regulators push the boundaries of regulation and their scrutiny into areas that are not subject to regulatory requirements (Black et al. 2007). Recognizing the benefits and the limitations of both rules and principles, Arjoon (2006) argues that effective and ethical corporate governance requires a combination of both approaches.

The Basel Committee on Banking Supervision and Bank Governance

The Basel Committee on Banking Supervision (BCBS) was set up in 1974 and comprises representatives of central banks and supervisors from several countries. This international standard setting body and forum is based at the Bank for International Settlements in Basel, Switzerland. The BCBS has published several international

banking standards and is best known for the prudential standards embodied in the Basel Capital Adequacy Accord. The BCBS started setting international guidelines and standards on corporate governance for banks in September 1999 (BIS 1999a). This publication was titled “Enhancing Corporate Governance in Banking Organisations” and was issued shortly after the OECD published a set of corporate governance standards and guidelines in June 1999 (BIS 1999a; OECD 1999). The OECD's standards were aimed at governments to support stock exchanges, investors, businesses, and other entities that were involved in establishing good corporate governance systems and practices. Since 1999, the BCBS has continued to review and revise its advice on corporate governance to keep abreast of developments and emerging trends in the banking sector.

The motivation for the BCBS to issue corporate governance guidelines for banks was to take account of the unique elements of banks that need to be recognized in corporate governance and to also provide support for the critical role good corporate governance plays in the proper functioning of banking supervision. Banks are deemed to have a fiduciary duty that goes beyond their obligation to shareholders and extends to multiple stakeholders such as depositors, creditors, bondholders, the society, and the environment (Macey and O'Hara 2003; De Haan and Vlahu 2016). Detecting and satisfying the expectations of these stakeholders in a way that creates shared value is a clear challenge for banks from strategic to operational levels (Formisano et al. 2018). Public confidence in banks is essential to maintain economic growth, financial stability, and sustainability. Good corporate governance would contribute significantly to incentivizing banks' managers and owners to undertake risk prudently, at levels that would not lead to instability or create social costs for other stakeholders and the wider economy (Alexander 2006).

The BCBS explicitly states that one group of bank stakeholders for whom the quality of bank governance has practical implications is bank supervisors. Supervisors have a mandate to mitigate the adverse effects of banks' activities and limit systemic risk. They achieve these goals by

evaluating banks' activities, by promoting good governance in banks, and by establishing the expectations for corporate governance. It is not surprising that following the 2008 global financial crisis international financial institutions like the BCBS have increased their focus on risk management, on reinforcing the oversight and risk governance role of bank boards and board committees, and on strengthening accountability and internal controls.

History and Development of the Basel Recommendations

The 1999 corporate governance guidelines issued by the BCBS targeted banking supervisors globally, with the aim of providing a tool for supervisors to promote good corporate governance practices among banks (BIS 1999a). Bank supervisors are responsible for checking that a bank is properly governed and for highlighting any shortcomings in bank's corporate governance practices to senior management. Prior to publishing these guidelines, the BCBS had issued publications on the management of interest rate risk, the management of credit risk, bank transparency, and internal control systems which highlighted and reinforced the importance of corporate governance to banks' strategies and techniques (BIS 1997, 1998a, b, 1999b). The 1999 corporate governance guidelines identified and set out seven areas of good corporate governance practice but did not refer to these explicitly as principles. The guidelines related to setting and communicating strategic objectives and corporate values; setting and enforcing lines of responsibility and accountability; board member qualifications and independence from senior management; senior management oversight; internal and external auditors; compensation and transparency of corporate governance. While noting the primary responsibility for corporate governance rests with the board and senior management, the important role of other players, such as governments, stock exchanges and securities regulators, auditors, and trade associations, in implementing good corporate governance is also acknowledged in the

guidelines. The 1999 corporate governance paper was divided into three clear sections titled practices, supervisors, and environment, respectively.

Following the OECD's reissue of a set of corporate governance principles in 2004, the BCBS revised its own guidelines in 2006 (OECD 2004; BIS 2006). The 2006 version was issued to both banking organizations and supervisors. The revised guidelines also paid specific attention to complex banking organizations and financial conglomerates that operate across jurisdictions and across several lines of business which results in them having structures that are not transparent. The 2006 publication paper followed a similar structure to the 1999 paper. Section 1 presented eight distinct principles; section 2 considered the role of supervisors; and section 3 commented on promoting an environment that is conducive to sound corporate governance (BIS 2006).

The 2008 global financial crisis acted as a catalyst of the release of the first post-crisis version of the BCBS corporate governance guidelines in 2010 (BIS 2010). The crisis revealed several corporate governance failures and weaknesses in banks. Kirkpatrick (2009) highlighted several areas of weakness that had contributed to the crisis. The flaws included weaknesses in risk management systems; compensation and incentive systems that encouraged risk taking; ineffective board oversight; gaps in disclosure and accounting standards and a flawed credit rating process. In response to the weaknesses identified, a key focus of the BCBS was curbing short-termism and excessive risk taking in banking. The principles were revised and expanded to 14 principles. These principles were set out in six different sections as follows:

- Section A: Board Practices – Principles 1 to 4 (overall responsibilities, qualifications, structure, group structures)
- Section B: Senior Management – Principle 5 (consistency of activities with risk appetite and strategy)
- Section C: Risk Management and Controls – Principles 6 to 9 (effective internal controls and risk, management function including a Chief

Risk Officer or equivalent, risk identification and monitoring, robust risk communication and reporting, use of work conducted by internal auditors, external auditors and internal controls)

Section D: Compensation – Principles 10 and 11 (design, operation and review of compensation systems, alignment between compensation and risk)

Section E: Complex or Opaque Structures – Principles 12 and 13 (board and senior management knowing and understanding structures and associated risks, understanding the risks of special purpose structures and jurisdictions that may impede transparency and steps taken to mitigate these risks)

Section F: Disclosure and Transparency – Principle 14 (transparency of governance to shareholders and stakeholders)

This breakdown shows that 8 out of the 14 principles are in the areas of board practices and risk governance. The guidelines were strengthened on the role, qualifications, and composition of boards and board oversight of compensation systems. The significance of the risk management function and the role of the chief risk officer were also emphasized. Furthermore, the importance of an understanding of banks' operational structure and risks by both the board and senior management was incorporated in the guidelines.

The 2015 Principles

Following consideration of the comments received on the consultative version of the principles in 2014, an updated version was published in July 2015 (BIS 2015). This version also considered recommendations made by the Financial Stability Board in its 2013 Thematic Review on Risk Governance about the board's role in risk governance and in establishing a risk culture in a bank (FSB 2013). The 13 principles include changes that provide more clarity, detail and guidance on the obligations of board members, board collective competence, the oversight and risk governance responsibilities of the board, the allocation of responsibilities between committees, senior

management and control functions, the key elements of a robust risk governance framework, and the internal control mechanism of banks.

The 2015 principles acknowledge that the primary role of a bank's board of directors is oversight. In this version, the requirement that the chairperson of the board of directors should not chair any board committee was removed. One of the ways in which these principles would be helpful to bank supervisors is that they can act as a guide for supervisors in how they assess the processes that banks have used to select their board members and senior management. There are important changes with regard to risk management and to compensation provisions for those who are deemed to be risk takers in banks. Compared to the preceding version of the guidelines, some aspects of the 2015 recommendations are worth noting because of their implications for responsible conduct and its regulation. In recognition of growing concerns about mis-selling and other scandals in banking, specific provisions on conduct risks are included explicitly in the responsibilities of board members and senior management (Ferran 2012; Financial Conduct Authority 2013; Zunzunegui 2018; Bugeja 2018). As trust and integrity are important for sustainability, a new feature of the guidelines is the recommendation in Principle 9 that banks establish a compliance function as a second line of defense that will support corporate values and ensure that banks act responsibly. The guidelines also specify roles for supervisors that will strengthen the global financial architecture that identifies and manages the risks that are inherent in a global financial system.

The 13 principles of the Basel Recommendations on Corporate Governance for Banks cover the following topics:

1. Board's overall responsibilities
2. Board qualifications and composition

Summary

The 2015 Basel Recommendations on Corporate Governance Principles for Banks are part of the developments that have evolved to create a more sustainable financial system. This would allow banks to play an effective role in financing sustainable development and in maintaining the financial stability that is needed for economic growth and development. Institutions such as the Basel Committee on Banking Supervision, the Organisation for Economic Cooperation and Development, and the Financial Stability Board are collaborating and cooperating to help promote financial stability through better bank governance and to end the problem of institutions deemed too big to fail. Strengthening bank governance by means of a principles-based approach to regulation is an ongoing process that will progress over time as bank boards adopt the appropriate oversight and develop the appropriate corporate culture, controls, risk management, and compliance systems that underpin good corporate governance.

Behavioural finance; Investor sentiment

Definition/Description

The holy grail of academic finance is to identify those factors that are best able to explain expected returns. The capital asset pricing model (CAPM) proposed by Sharpe (1964) and Lintner (1965) sought to calculate the risk premia inherent to financial assets. Researchers correspondingly study a variety of risk factors to best explain and predict the expected returns, including works by Fama and French (2016, 2018), and Barillas and Shanken (2018) among many others. In addition to company fundamentals and the macroeconomic environment, a new branch of finance has emerged for forecasting expected returns based on investor sentiment as one of the main drivers inducing return co-movements. Optimism or pessimism may drive investor behaviors that condition their interactions with the markets and therefore impacting on stock returns. This investor sentiment can derive from their belief or otherwise in the future performance of companies and economies. Consequently, beyond providing a financial context for market behaviors, sentiment also shapes the overview of the prevailing health of economies.

How best to measure investor sentiment is a recent but wide-reaching debate in academia (Zhou 2018). According to Pompian (2011), behavioral finance emerged as a specific academic and professional field in the wake of the works by Professors Daniel Kahneman and Vernon Smith who culminated in their receiving the 2002 Nobel Prize for their contribution of having integrated psychological research into economic science. Professor Kahneman, along with Professor Amos Tversky, put forward prospect theory as capable of returning better accounts of the behaviors observed (Kahneman and Tversky 1990). Given the impossibility of measuring sentiment directly, proxy measures are adapted to this end and potentially enable the predictability of asset prices. The sentiment measures coexisting today approach market data, survey data, and text analysis data (social, Internet, and media information on markets). There has hitherto been no unanimous consensus as to the best proxy measure

either for sentiment or for forecasting market movements and co-movements. However, the Baker and Wurgler (2006, 2007) market sentiment index remains one of those most commonly applied.

Background

Financial market movements and co-movements are also shaped by sentiment, especially during periods of irrationally unjustified panics or exaggerated optimism. Sentiment maybe defined as the deviation bias between the theoretical asset price as sustained by its fundamentals and its current price (Benhabib et al. 2016; Piccione and Spiegler 2014). Stock prices thus turn irrational whenever the market is moved by (irrational) investor sentiment. Accordingly, the Fama (1960) efficient market hypothesis, characterized by a market with overwhelmingly well-informed investors, properly priced investments that reflect all of the information available will simply never prevail. Hence, contagion, crisis spillover, or market co-movements all represent evidence of the relevance of investor sentiment. Market data-based measures of sentiment include closed-end discount funds, dividend premiums, stock turnover rates, IPO numbers, trading volumes, VIX sentiment (the implied volatility of S&P500 options), and new account numbers, among others (Chen et al. 2019). Survey data provides another means of measuring sentiment in accordance with the results of investor surveys on market prospects with the most common such inquiries being the University of Michigan Consumer Sentiment Index, Investor Intelligence, the American Association of Individual Investors (AAII), and the EUROSII sentiment (which is the Eurozone Sentix Investor Confidence) for the European context. In terms of the text data approach, this type of sentiment measure applies word recognition to evaluate the incidence of predetermined terms in social media data and on social networks such as LinkedIn, Facebook, Twitter, and Instagram. Thomson Reuters, for example, runs a text data sentiment index called

MarketPsych. Machine learning and AI (artificial intelligence) techniques are opening up new paths for quantitative fund managers to derive value from traditional and nontraditional data sources, in particular text data. Nevertheless, irrespective of the utility of the resulting indexes, accounting and finance text data studies are subject to criticisms that include their lack of transparency and the failure to replicate their results (Loughran and McDonald 2016). However, understanding how investor psychology impacts on stock market returns holds the utmost importance to better any understanding of markets, especially as regards the predictive powers of investor sentiment.

Summary

Behavioral finance applies the field of psychology to finance and became the focus of many studies in the wake of the tech-stock bubble in 2000 (Pompian 2011). Human emotions (investor psychology or cognitive psychology provoking excessive euphoria or fear) and cognitive errors in financial decision-making create psychological biases when assessing the future performance of stock markets, driving fluctuations that generate instability. Behavioral finance studies the irrational behaviors or biases of individual investors and correspondingly investigates the irregularities in the efficient market hypothesis.

Benchmarking

Andrea Venturelli
Department of Economic Sciences, Università del Salento, Lecce, Italy

Synonyms

[Emulation](#)

Definition

The origin of the concept of benchmarking was introduced to describe the financial phenomenon from a strategic perspective. A preliminary definition of benchmarking was provided by Camp (1989) who defines benchmarking as research of best practices in order to achieve higher performance. From his perspective, benchmarking consists of a philosophical approach to firms' activities due to their exigence to identify the best in class competitors in order to measure in a comprehensive and consciousness way their performance. Specifically, the contribution of Camp supports one of the most appreciated philosophical quotes proposed by Sun-Tzu (1963) that said: “If you know the enemy and know yourself, you

need not fear the result of a hundred battles. If you know yourself but not the enemy, for every victory gained you will also suffer a defeat. If you know neither the enemy nor yourself, you will succumb in every battle."

Prior studies denoted how since 1940, studies on this topic have been characterized by five different degrees of sophistication about the reason behind the adoption of these practices (Watson 1993). The author suggests how during the period between 1940 and 1990, we observed a passage from "reverse benchmarking" activities oriented to analyze products' characteristics to "global benchmarking" activities oriented to understand the strength and the weakness of an entire enterprise. Moreover, recently, academics identified a potential "sixth phase" called "learning benchmarking" or "bench-learning" (Kyrö 2003). The aim of these new practices is to develop new competencies through a deep analysis of competitors.

Benchmarking Indicators

Benchmarking consists of the identification of a multidimensional set of indicators that represents and describes competitor characteristics. In fact, the analysis of performance could not be conducted only on a set of specific indicators because from a theoretical point of view every firm has its own strength and weakness. In this sense, the comparative analysis allows the manager to identify a new operational paradigm in order to gain, repair, and maintain their strength. Moreover, the analysis of this concept was conducted even by consulting firms due to the increasing attention paid by them to this topic in their services. Their attention has been favored by the new exigencies of the firms that, contrarily to the past, start to consider in their business models further aspects not strongly related to financial performance such as nonfinancial aspects and relationship with their stakeholders. In this sense, benchmarking needs a strong connection between theory and praxis in order to identify a set of measures useful for analysts to understand the effective context where their firms operate.

According to this evidence, academics identified four pillars that describe clearly the focus of this practice. These four pillars are represented by reciprocity, processes' similarity, processes' evaluation, and evaluation's legitimacy. The principle of reciprocity consists in the implementation of friendly connections between firms and observed firms in order to favor the exchange of information between them. In this sense, a true benchmarking process could not exist without a two-way exchange of information between the parts involved. The principle of similarity is obvious in a process of evaluation, and it consists of a prior selection of activities characterized by similar paradigms in order to favor their comparison. The principle of a praxis' evaluation consists of the effective identification of a set of best in class firms and by their relative analysis. In this sense, as evidenced before, this process currently is typically data driven due to the existence of new digital tools like blockchain that allow analysts to find information through data-mining activities (Hamida et al. 2017). Finally, the last pillar is represented by evaluation's legitimacy that represents the validation of the analysis goodness. In this sense, the legitimacy of evaluation systems could be measured through the adoption of a set of common standards.

Benchmarking and Sustainable Development

The socioeconomic implications that characterize the current scenario have imposed enterprises to redefine their paradigms through new strategies. One of the most appreciated strategies adopted worldwide by them is represented by benchmarking. In this sense, during the last few years, the concept of benchmarking has been widely analyzed by academics that operate in different fields of study. In fact, the literature on benchmarking is not strictly related to business and management fields but is extended to other areas such as engineering, chemistry, and medicine. In this sense, the multidisciplinary aspects that characterize sustainable management allowed academics that operate in different fields and

contexts to apply this theoretical framework to nonfinancial aspects.

The relevance of benchmarking on sustainable practices regards not only academics but also new categories of stakeholders. In fact, the recent scenario is characterized by several attentions paid by policymakers, NGOs, and investors to these practices. In this sense, the increasing attention paid by stakeholders on sustainability practices represents a new area of analysis for academics and practitioners in order to identify the new protocol to improve the degree of transparency about nonfinancial aspects connected to entities activities. In fact, as evidenced by prior studies, one of the most important aspects connected to the adoption of sustainability practices consists of the value relevance of these practices. In this sense, this theoretical evidence has been supported by the recent environmental scandals where the disclosure of negative information about firms' sustainability impacted negatively on firms' market value. A typical example of this phenomenon is represented by Volkswagen's case where after the scandals the share's market price decreases consistently. In this sense, the last few years were characterized by the rapid growth of socially responsible investments (SRI), which represents a new market segment for financial analysts. In this sense, to improve the degree of comparability between socially responsible firms, rating's agency introduced new ethics indexes in order to give to each fund a score that represents its behavior. According to this evidence, benchmarking covers a central role in sustainability due to the coexistence of different expectatives about firms' socially responsible practices.

One of the most important contributions in terms of development of benchmarking practices has been proposed by the United Nations (UN). Since 2015, the UN introduced 17 Sustainable Development Goals (SDGs), composed of 169 targets, in order to achieve better condition for all before 2030. Specifically, SDG 12.6 highlighted the relevance of reporting in order to sustain the achievement of better condition. In this sense, the content of SDG 12.6 is as follows: "*Encourage companies, especially large and*

transnational companies, to adopt sustainable practices and to integrate sustainability information into their reporting cycle." The definition of this goal by the UN represents a strategic driver to the adoption of benchmarking practices by firms due to the highest availability of information about nonfinancial aspects produced by firms inspired by this principle. Moreover, standard setters have introduced a new form of frameworks in order to harmonize the content of nonfinancial reports inspired by SDGs. In this sense, Global Reporting Initiative (2015) introduced a set of standards that describe SDGs through the combination between different nonfinancial indexes. This contribution has been relevant as evidenced by Oxfam (2018) who denoted how firms' activities on sustainable development are not ever followed by effective communication. In this sense, a large part of them discloses information characterized by a lack of credibility due the absence of common reporting standards. In fact, prior studies denoted how the adoption of a set of large adopted standards increases the degree of credibility connected to nonfinancial information. Moreover, their adoption decreases the risks of greenwashing and abuse of impression management strategies by managers (Brockhaus et al. 2016).

In this sense, internal and external stakeholders currently need more information than in the past due to the increase in sensibilization on this topic. Specifically, managers need information about their firms in order to adequate their business models through an internal benchmarking analysis. Furthermore, managers need information about competitors' practices in order to acquire knowledge from them through an external benchmarking analysis. In this sense, this evidence denoted how the comprehension of this phenomenon in sustainability management needs a strong orientation by the manager to these practices. In fact, as evidenced before, one of the most important principles in benchmarking is represented by reciprocity. However, from a managerial perspective, firms are typically not oriented to act in a reciprocity way with external stakeholders due their

skepticism to share negative information with them. A typical example is represented by the healthcare sector where managers prefer to not disclose information about the average number of deaths due the risks of benchmarking analysis by their patient (Lilford and Pronovost 2010).

According to this evidence, a central role is covered by nonfinancial reporting. In fact, prior studies highlighted how the increasing of the average number of nonfinancial reports published yearly impacts positively on stakeholder's ability to compare entities' sustainable performance (Milne and Gray 2013). Finally, the different categories of stakeholders interested by firms' activities need information about their nonfinancial performance in order to judge the gap between their expectative and firms' behaviors (Skouloudis et al. 2012). However, practitioners denoted how even if in the absence of worldwide mandatory provisions about nonfinancial reporting, an increasing number of firms started to adopt nonfinancial reports voluntarily (KPMG 2017). Moreover, the introduction of new regulation about mandatory nonfinancial reporting has increased the degree of transparency of information about firms' nonfinancial impacts. In fact, the provisions of a set of common rules about nonfinancial reporting in contexts such as Europe and South Africa allowed academics, analysts, and managers to make an internal and external comparison between periods, sectors, and country (Venturelli et al. 2019; Doni et al. 2019). A central role in the process of harmonization about firms' nonfinancial reports has been covered by Global Reporting Initiative (GRI) that introduced a set of common reporting standards in order to improve the degree of comparability between nonfinancial reports. Furthermore, GRI prepared a set of sector-specific standards in order to evaluate in a more effective way firms' behavior. In this sense, despite the general orientation of worldwide regulators is to introduce a new form of soft regulations to achieve an adequate degree of harmonization without a substantial standardization, country-specific studies highlighted how the most common standard-setters adopted by firms to prepare their reports are represented by GRI. This evidence favors the achievement of the

four benchmarking pillars evidenced in the previous section. In fact, the adoption of common standards by a large part of the firms interested to adopt nonfinancial reports in a voluntary or mandatory way responds to the requirements of reciprocity, similarity, effective evaluation, and legitimacy.

Key Issues

Although nonfinancial reporting remains a typical voluntary activity, policymakers have begun to introduce a new form of regulations in order to increase the average number of nonfinancial information yearly disclosed by entities. However, despite the quick increase of nonfinancial reports published, the current scenario is characterized by low attention paid by worldwide firms to this topic. In particular, this negative phenomenon regards SMEs that are typically not oriented to adopt voluntarily these practices. In fact, SMEs typically perceived nonfinancial reporting as a practice not adequate to their business. Moreover, another category that is typically not oriented to adopt nonfinancial reports is represented by state-owned enterprises (SOEs). Specifically, prior study evidenced how the peculiarities of their activities influenced negatively their orientation to adopt nonfinancial reports prepared according to the Global Reporting Initiative standards. In this sense, benchmarking on sustainability practices still represents an activity that typically regards large firms that operate in private sectors due to the physiological lack of data connected to SMEs and SOEs. In this sense, the increasing attention paid by policymakers to nonfinancial reporting represents a strategic driver in order to ensure the achievement of this topic.

Furthermore, a central role is covered by the United Nations. In fact, as evidenced before, the clear identification in SDGs 12.6 of nonfinancial reporting as strategic driver represents an important element to improve the attention paid by public and private stakeholders to sustainability topics. In this sense, the recent data provided by practitioners denoted how public and private

sectors started to adapt their strategies to principles inspired by ethics.

However, the worldwide diffusion of benchmarking practices about sustainable activities needs a physiological cultural change by managers. In fact, as denoted by prior academics that analyzed for the first time this topic, benchmarking impacts on corporate governance because its implementation needs a subsequential orientation to new operation paradigms (Camp 1989). In this sense, managers must adapt their behavior to benchmarking's principles. Furthermore, other studies evidenced how the adoption of practices inspired by benchmark principles represents a strategy that impacts positively on firms' ability to engage in an effective way with its stakeholders. Specifically, prior studies denoted how benchmarking acts as an intermediary between firms and external stakeholders that represent a "*specific environment*" which impacts on firms' performance (Robbins et al. 2008). In this sense, its main role is represented by the ability to improve firms' knowledge about market complexity.

Summary

The topic of benchmarking in sustainable management represents a new field of study for academics due to the prominent role covered by public and private sectors in order to achieve an adequate level of worldwide sustainable development. However, as evidenced in the previous sections, studies on benchmarking are currently based on prior researches based on financial performance. In this sense, the topic needs a new contribution by academics in order to identify new paradigms to analyze this topic from a sustainability point of view. In this sense, a strong connection between academics that operate in different fields of studies represents a strategical driver for the achievement of these topics. Moreover, the great attention paid by public and private entities to a new form of accountability such as nonfinancial reports and integrated reports increases the degree of information about the sustainable practices adopted by them. In this sense,

the role of policymakers and think tanks will be strategical in order to increase the number of entities that prepared yearly nonfinancial reports. Furthermore, the introduction by standard setters of a new form of reporting framework represents an important element in order to improve the degree of comparability between information provided by firms that operate in different context and sectors.

From a methodological point of view, the rapid growth of Big Data represents an important tool to improve the ability of stakeholders to make benchmarking between two or more entities. In this sense, the contribution of academics will be relevant in order to identify a new paradigm useful for managers and practitioners to activate a new form of benchmarking. Furthermore, digitalization will be a strategical driver to identify new operational paradigms to increase the degree of comparability between and within entities (Ebner et al. 2016). Nowadays, benchmarking practices have been characterized by a rapid growth favored by the introduction of new technologies such as Internet of Things (IoT), Blockchain, and Big Data that allows firms to acquire in an easy way information useful for their internal and external analysis (McKinney et al. 2017).

According to this evidence, the introduction of benchmarking praxis about nonfinancial practices will be easier than in the past due to the major attention paid by stakeholder and due to the existence of new evaluation tools. In this sense, future research will identify a new frontier of analysis and new operational paradigms in order to achieve a higher degree of data comparability. Moreover, started from the most recent research, the new challenge for academics will be connected to the identification of a new type of benchmarking practices characterized by a higher degree of sophistication.

Benefit Corporations

Giorgia Nigri

Department of Economics, LUMSA, Rome, Italy

Synonyms

Hybrid companies; Social purpose companies

Definition

Benefit corporations are for-profit companies that commit to creating a benefit in addition to their for-profit motive. The benefit corporation status is a corporate legal form that was introduced in 2010 in Maryland, giving directors and officers the legal protection to pursue a public benefit. The Benefit Act requires boards to consider environmental and social factors as well as the financial interests of shareholders. In most states, benefit corporations are required to publish an annual benefit report that includes an assessment of the overall social and environmental performance against a third-party standard to help the company, management, governance, shareholders, and the general public determine whether it has met the declared benefit in its statutory corporate purpose. The B Corp B Lab certification, on the other hand, is a seal of fitness to the standards. To become certified B Corps, companies have to achieve a score of 80 or above on the B Lab platform by taking an online assessment. The Benefit Impact Assessment (BIA) measures a company's overall impact by analyzing the business model and the following areas: workers, community, environment, customers, and governance. Once the process evaluates the global impact of the business, the company that completes the assessment can

add the B Corp certification to its products and website. Lastly, the B Corp Benchmarks help to compare and improve a company's social and environmental performance.

Introduction

The financial, social, and environmental crisis experienced in the twenty-first century has brought to wealth inequality, climate change, and social unrest and has led to the need to rethink business and economics. The shareholder supremacy model that has been advocated for so long by both practitioners and academics has damaged entire communities and depleted natural resources, creating severe risks for the living conditions of future generations (United Nations 1992) and species (Laszlo 2019).

This brought to a profound transformation of the economic and social ecosystem to take place where (Nigri and Del Baldo 2018; Nigri and Michelini 2019) attention is drawn to social and environmental outputs and not only to economic outcomes (Hiller 2013; Nicholas and Sacco 2017).

Governments and the nonprofit sector alone cannot affect large-scale systemic change. For-profit business, on the contrary, can attract capital and talent at scale accelerating a global culture shift and build a more inclusive and sustainable economy (McNulty Foundation 2015). Companies today – in line with the Sustainable Development Goals (SDGs) of the United Nations 2030 Agenda – are thus expected to become actors of change and value creation (Nigri et al. 2016).

B Lab – a third party such as the US Green Building Council, Underwriters Laboratory, Green Seal, or Global Reporting Initiative (Nicholas and Sacco 2017) – where B stands for Beneficial (Steiman 2007), pursues this goal by creating a network and an infrastructure that can help support this economic transformation.

Brief History

B Lab's founders, Jay Coen Gilbert, Andrew Kassoy, and Bart Houlihan, all attended Stanford

University in the 1980s and different years later became Henry Crown Fellows of the Aspen Global Leadership Network (AGLN) (McNulty Foundation 2015). As roommates and friends, in 1993, Jay and Bart founded AND1 – a footwear and clothing company specializing in basketball attire and tapes – together with Seth Berger and Tom Austin (Dent 2016). By the 2001 season, AND1 was second only to Nike. As a company, it had grown not only its market share but also its socially responsible activities. They implemented shared ownership programs and promoted high-quality urban education and youth leadership by financing – with 5% of profits annually – programs with local charities. They also posed great attention to employees and worked with overseas factories to implement a supplier code of conduct ensuring worker health and safety, fair wages, and professional development (Honeyman 2014).

After a credit crunch and a few layoffs, in 2005, when the company was back on track, they finally decided to sell to American Sporting Goods (Hartford 2005), and within a few months' time, the company's preexisting commitments to its employees, overseas workers, and local community were eliminated (Honeyman 2014). It was this drive, the Henry Crown Fellowships, and their network and relationship that pushed them to search for a different paradigm. They wanted stakeholders – employees, communities, and people affected by the business – to matter as much as shareholders. They thus founded B Lab (McNulty Foundation 2015), a nonprofit organization that uses business as a force for good (Honeyman 2016), together with Andrew, who had only been an investor in the AND1 project and was now ready to support them fully, after spending 16 years in private equity.

B Lab, therefore, began by building an independent certification and the market infrastructure to help it scale (Di Cesare and Ezechieli 2017). All companies could aim to be like the original AND1. The for-Benefit model (Castellani et al. 2016) they had in mind could help capitalism work for the long term to the benefit of all (Honeyman 2016; Schaw 2017) and drive a global cultural shift by redefining success in business. By creating a community of certified benefit

corporations, B Lab aims to build a more inclusive and sustainable economy (Fierro and Miller Hill 2016) with specific values and aspirations embedded in the B Corp Declaration of Interdependence (B Lab 2019a).

B Lab's initiatives today include the B Corp Certification, the administration of the B Impact Management programs and software, stakeholder management tools like the Benefit Impact Assessment (BIA) (Steiman 2007; B Lab 2018a), and advocacy for governance structures like the benefit corporation legal framework (Hiller 2013; Baudout et al. 2018).

Legal Framework, Certification, and Report

Benefit corporations and certified B Corps represent alternative models of enterprise, often referred to as hybrid companies that bridge the for-profit and not-for-profit models (Billis 2010; Baudout et al. 2018). Although their goal remains the same, benefit corporations and B Corps are two different phenomena which must be outlined separately (Nigri et al. 2016).

Benefit corporations are for-profit companies that commit to creating a benefit in addition to their for-profit motive (Bauco et al. 2017) and have formally agreed to do so by incorporating as a benefit corporation or adding the benefit in their company motives, giving it a binding, legal statute.

The benefit corporation status is a corporate legal form that was introduced in 2010 in Maryland, giving directors and officers the legal protection to pursue a public benefit (Hiller 2013). The Benefit Act (US Law 2010) requires boards to consider environmental and social factors as well as the financial interests of shareholders (Stecher et al. 2012). This corporate form provides companies that want to act in the public interest governance processes and access to investment capital (Baudout et al. 2018).

In most states, benefit corporations are required to publish – it does have to be audited or certified – an annual benefit report that includes an assessment of the overall social and

environmental performance against a third-party standard to help the company, management, governance, shareholders, and the public determine whether they have met the declared benefit in their statutory corporate purpose. As of today, most benefit corporations utilize the B Lab framework (B Lab 2019b) when preparing their annual benefit reports even though the benefit corporation legislation does not require benefit corporations to adopt any specific third-party standard – any third party can provide the standard. The law states that the standard must abide by specific outlined characteristics and must be independent and credible and respect accountability and transparency provisions (US Law 2010).

The purpose of the benefit report serves de facto to meet the transparency and accountability provisions of the benefit corporation legislation: inform the public about the overall impact and performance of the benefit corporation, assess the progress of directors, and give stakeholders the possibility to exercise their rights. In a benefit enforcement proceeding, for example, judges may look at a benefit report, or at a series of annual benefit reports, to determine if the benefit corporation has met its statutory requirement to meet its general, and any named specific, public benefit purpose.

The B Corp B Lab certification, on the other hand, is a short-term seal of fitness to the standards (Nicholas and Sacco 2017) which measures a company's balance between profit and purpose. A Certified B Corp is thus a business that meets social and environmental performance, public transparency, and legal accountability standards, verified by B Lab, through the benefit impact assessment (Fig. 1).

The Benefit Impact Assessment

Therefore, certifying as a benefit corporation goes beyond product- or service-level certification. To become certified B Corps, companies must achieve a score of 80 or above on the B Lab platform by taking an online assessment (Nigri et al. 2016) which evaluates how a company's

Benefit Corporations, Fig. 1 Graphic representation of benefit corporations and B Corps

operations and business model impacts workers, the community, the environment, and customers.

These areas consider the impact that the company may generate, the standards and certifications it has obtained, implemented in-house practices, community involvement, and value chain activities (Nigri 2018). The assessment ranges from supply chain management and input materials to philanthropic charitable giving and employee benefits.

Workers

The worker impact measurement focuses on three main aspects: (1) compensation, analyzing sector average salaries and comparing the salary levels and benefits granted to executives with those given to employees; (2) benefits, such as

supplementary retirement plans and health services, smart working, childcare, flexibility, and stock options; and (3) training, concentrating on professional development, turnover, health, and safety. Finally, company ownership and employee engagement through an employee handbook and anonymous satisfaction surveys are included in the evaluation (Honeyman 2016). In detail:

Community

The community impact measurement focuses on five areas: (1) job creation, for example, a recruitment policy that is attentive to the local dimension and to chronically underemployed social groups; (2) diversity, i.e., a board of directors, a team of managers, a staff, and a supply chain in which the

usually marginalized categories are adequately represented; (3) civic engagement and philanthropy, i.e., support for employee volunteering activities and charitable donations; (4) involvement at the local level, such as appealing to local and independent financial institutions and supporting local businesses, owned by members of ethnic minorities or women; and finally, (5) the suppliers, distributors, and products area, which includes aspects such as increasing transparency thanks to the dissemination of the social and environmental performance of the supply chain (Honeyman 2016) to all stakeholders.

Environment

The environment impact measurement focuses on four areas: (1) the land, offices, and plant area, which includes improving efficiency in water and energy consumption and waste generation, using renewable energy, encouraging employees to use ecological home/work transport alternatives, and improving indoor air quality for company buildings; (2) the energy, water, and materials area, which includes, among other things, the performance of a product life-cycle assessment; (3) the emissions and waste area, which consists of the launch of a plan for the recovery and reuse of products and the monitoring of greenhouse gas emissions; and (4) the transport, distribution, and supplier area, which includes the ability to incentivize suppliers to improve their environmental performance (Honeyman 2016).

Governance

The governance impact measurement focuses on three main areas: (1) the mission, which includes the inclusion of a commitment to sustainability in the declaration of intent and on the mission itself, the training of personnel on environmental and social values, and the request for feedback to stakeholders; (2) transparency, which includes the sharing of economic and financial information with employees, the presentation of an annual report, and collaboration in the development of social environmental standards within the business sector; and (3) the corporate form, to verify

if the company has formally integrated its mission in the statute (Honeyman 2016).

The process involves inserting company data, such as previous certification, partnerships, and questionnaire results, into the algorithm developed by B Labs' Standards Advisory Council (SAC) (Bauco et al. 2017), an independent committee of 20–22 members, each with deep industry or stakeholder expertise (Nigri 2018). The SAC is divided into two subgroups – one to oversee the content and weightings for the version of the B Impact Ratings System (B Lab 2019c) for companies and funds in developed markets and the other for emerging markets (B Lab 2018b).

Once the process evaluates the global impact of the business, the company that completes the assessment process (which lasts about 6 weeks) can add the B Corp certification to its products and website (Nigri 2018; B Lab 2016).

Summary

The B Corp certification pinpoints where a company excels in the short term, and the benefit corporation governance framework commits to consider stakeholder impact for the long term by building it into its legal structure (Di Cesare and Ezechieli 2017). BIA results give specific impact indications that can be utilized to prepare the annual benefit report (B Lab 2017) and as a benchmark to compare and improve a company's social and environmental performance against peers (B Lab 2019b).

Over the next 3 years, thanks to a partnership between B Lab and the UN Global Compact, the B Corp Benchmarks system will help companies assess their performance against Sustainable Development Goals (SDGs) comparing them to tens of thousands of other companies in B Lab's database.

B Lab and the UN Global Compact have an agreement to collaborate to create a free publicly available online management platform, key indicators, and resources available for companies to improve their impact. The plan is to reach 100,000 companies by 2030 in partnership with other

institutions and networks aiming to help businesses deliver on the SDGs (ASVIS 2018).

Big Data and Data Mining

Alexandra Korcheva
Sofia University “St. Kliment Ohridski”, Sofia,
Bulgaria

Synonyms

[High volumes of data](#); [Large amounts of data](#); [Large amounts of information](#); [Large quantities of data](#); [Lots of data](#); [Massive data](#); [Three Vs](#)

Definition/Description

Big data refers to a large volume of data that is gathered and stored in digital format. Because of their size, datasets that are gathered can be utilized and analyzed only through special techniques.

Despite not having a single valid definition of how big a dataset should be in order for it to be qualified as big data, most professionals agree that big data should have the so-called three Vs – volume, variety, and velocity (Smiley 2016). Big data can be structured, semi-structured, and unstructured.

Data mining refers to the process of extracting knowledge from large datasets. It is essentially discovering and analyzing hidden patterns in data, from where the mining metaphor comes from (Wu et al. 2009).

Data mining algorithms can be supervised or unsupervised. There are different types of algorithms that can be applied for discovery of knowledge from data – classifier, regression, clustering, association, sequential analysis, time series, dimensional reduction, etc. Each algorithm serves for discovering meaningful patterns of behavior that are hidden in data (Dataflok 2020).

Big data and data mining techniques have applications in many fields of business and research. As the amount of data that is collected grows, more and more entities – companies, governments, and research institutes – turn to data analysis in order to find hidden patterns of behavior and acquire more knowledge of relevant processes that may not be apparent or proven by more traditional methods of knowledge discovery (Smiley 2016).

Big Data

Big data has established itself as one of the main ways in which different patterns of hidden behavior can be identified. For this reason, it has been considered that big data analysis is a useful tool for cost minimization and profit maximization in business. It is more and more applied by organizations in the public and private sectors in order to gain insights that lead to better decision-making and improving strategies. Big data analysis is also gaining large popularity in various fields of scientific inquiry (Smiley 2016).

Despite not having a single definition on how much data can be considered big data, both theorists and practitioners agree that the big data should adhere to the three Vs of big data:

- Volume: refers to the amount of data or the size of datasets
- Variety: refers to different types of data
- Velocity: refers to how fast data is growing (Smiley 2016)

In some instances, two additional Vs are added to the initial three: veracity, whether the data can be trusted or not, and value, whether the data which we are storing and processing is worth the investment in terms of value of analysis insights (Tole 2013).

Challenges of Big Data

- Storage – storing large amounts of data creates the need for specific infrastructure that could often be costly (Mazumdar et al. 2019).

- Processing – specialists with specific skills are required in order to perform analysis of big data (Mikalef et al. 2018).
- Personal information regulation compliance – privacy and use of personal data have become one of the main issues in data handling. The privacy issue has both ethical and economic debates.

Perhaps some of the biggest challenges in big data, however, are not of technical nature but are rather socioeconomic issues. The use of big data in social-scientific analysis has raised a number of ethical concerns. Such concerns involve the necessity of signed consent forms of participants (Trilling 2017). Privacy and anonymization of the dataset are another related problem when using big data for social research. Even if pieces of information such as names or identity numbers are stripped from a dataset, people still might be identifiable (Trilling 2017).

Reproducibility of research results is also challenged due to legal restrictions and because big data is often dynamic in nature (Trilling 2017). Also, the size of the data is often too big, and in order to be able to reproduce the research techniques used in a study, researchers would need a specialist hardware for storage of data, etc. (Trilling 2017).

Data Mining and Data Mining Algorithms

Data mining is a combination of operations that data analysts apply to a dataset. The idea of data mining is to obtain information on often hidden patterns of behavior and find dependencies between variables (Wu et al. 2009).

Data mining algorithms are split into supervised learning algorithms and unsupervised learning algorithms.

Some main algorithms that are used in order to obtain meaningful insight from datasets are:

- Classification: These algorithms put the data into various classes based on their attributes (Datafloq 2020).

- Clustering: These algorithms divide data into clusters on the basis of some similar properties (Datafloq 2020).
- Association: These algorithms find correlation between attributes in data, on the basis of which they attempt to create association rules which are then used for predictions (Datafloq 2020).
- Sequence analysis: Finding frequent sequences in data.
- Regression: A mathematical model used to establish correlation or to predict behavior based on the data available.
- Time series analysis: A mathematical model that incorporates seasonal cycles.

Challenges in Data Mining

Development of data mining has led to unique challenges from the perspective of processing and analysis (Aggarwal 2015, p. 3). Some of the major challenges concern (Kade 2019):

- Data mining algorithms perform differently on bigger sets; therefore a scaling challenge is sometimes posed.
- Combinations of different types of complex data could be challenging, and data could often be noisy or incomplete.
- Protection of data security, integrity, and privacy is an ever growing issue.

Summary

Big data and data mining are considered to be highly valuable in terms of better understanding of the processes in both business and society. In the more and more data-driven economy, using data analysis has become a necessity for companies. It is by harnessing the power of gathered data that many organizations find new ways of optimizing their strategies. However, it is of most importance to have a transparent and fair way of collecting and using data, especially when it is related to individual behavior and individual choice.

Biodiversity

Stefania Massari, Federica De Leo, Pier Paolo Miglietta and Marcello Ruberti
University of Salento, Lecce, Italy

Synonyms

Biological diversity; Ecological diversity; Ecosystem diversity; Variety of living things

Definition

Biodiversity is an abbreviation for biological diversity and it represents the variety of life. There is a growing recognition that biodiversity represents a resource with enormous value for present and future generations. The Convention on Biological Diversity defines biodiversity as “the variability among living organisms from all sources including terrestrial, marine, and other aquatic ecosystems and ecological complexes of which they are a part: this includes diversity within species, between species and of ecosystems” (CDB 1992).

It is possible to distinguish three different hierarchical levels of biodiversity: genetic, species, and ecosystem diversity.

The first one is the genetic variation within a species, and it is the basis of a population’s adaptive capacity to environmental stresses.

Species biodiversity refers, instead, to the variety of species within a region, and its easiest measure is the number of species present in the area per unit (the greater is the richness of the species, the greater is the species diversity). To evaluate species biodiversity, however, it is also essential to consider species uniformity, given that not all species coexist in an environment of equal numbers: some are rare, some are popular, and

others are abundant. Regions with a higher number of species, with more uniformly distributed individuals, are those with greater species biodiversity.

Ecosystem diversity is the largest scale of biodiversity and describes the number of niches, trophic levels, and different ecological processes that maintain energy flow, food webs, and the recycling of nutrients.

The Dimensions of Biodiversity

The Convention on Biological Diversity defines biodiversity as “the variability among living organisms from all sources including terrestrial, marine, and other aquatic ecosystems and ecological complexes of which they are a part: this includes diversity within species, between species and of ecosystems” (CDB 1992).

The well-being (see) and productivity of all ecosystems, on which humans depend, are influenced by the environment around them in which there are different plant and animal species. The sum of all living organisms (microorganisms, plants, and animals), the genes that they have, and the complex ecosystems that they constitute in the biosphere represent the biodiversity that can be defined as the wealth of life on Earth.

The Earth’s biota is made up of an estimated ten million species (Pimm et al. 1995), whereas UNEP estimates that the possible global total of species amounts at approximately 14 million of which about 1.75 million species have been described and named to date, the others are unknown and undescribed. The most described species are animals (1,320,000 described and 10,600,000 estimated) and plants (270,000 described and 300,000 estimated), covering a total of 90% of the described species, while the currently less identified species are bacteria, for which there is also the greatest gap between described species and estimated species (4,000 described species compared to the estimated 1,000,000) (CBD 2001). There is, therefore, a large portion of unknown biodiversity associated with a loss of biodiversity caused by the extinction of many species. The present extinction rate of species is about 1000 to 10,000 times higher than the natural one (Pimentel et al. 1997). The International Union

for the Conservation of Nature (IUCN) has carried out a species extinction risk assessment, identifying different threat categories with an increasing risk of extinction in the short or medium term (least concern, near threatened, threatened, and extinct) (Pimm et al. 2014). By March 2014, IUCN had evaluated 71,576 species (mainly terrestrial and freshwater ones) and their related risk of extinction, observing that 860 were extinct, while 21,826 are threatened with extinction and, among these, 4,286 are endangered. The most threatened species were the terrestrial ones, with values ranging from 13% (birds) to 41% (amphibians and gymnosperms), while for freshwater species, the threat levels ranged from 23% (mammals and fish) to 39% (reptiles).

In addition to the decline in the number of species on the planet, changes that represent loss of biodiversity can also be considered:

- Conversion of biomes (of the 14 terrestrial biomes, two thirds of two and more than half of four have been converted to agriculture since 1990).
- The distribution of species on land is increasingly homogeneous.
- Genetic diversity has decreased globally, especially among cultivated species (MEA 2005).

The main factors for biodiversity loss are the destruction, degradation, and fragmentation of habitats, caused both by natural disasters (volcanic eruptions, tsunamis, floods, etc.) and by profound changes caused by human activities (climate change (see), pollution (see), overexploitation of natural resources, introduction of exotic species, deforestation, and habitat loss).

The Value of Biodiversity

Biodiversity is increasingly recognizable as the core of healthy ecosystems as biodiversity loss reduces multi-trophic interactions. The conceptual guiding principle behind the interconnection between biodiversity, good environmental condition, and human well-being is:

biodiversity → ecosystem functioning (EF) → ecosystem services (ES) → human well-being.

This consequential flow is based on the assumption that the increase in biodiversity has a positive effect, at least to some degree, on the functioning of the ecosystem, which increases ES and can finally enhance human well-being (Pinto et al. 2014).

The diversity of genes, species, and ecological processes makes a vital contribution to the functioning of ecosystems supporting their structure and processes (e.g., water, nitrogen, and carbon cycles are made possible by different species working to maintain ecological processes, and pollinators provide substantial benefits to the diversity of ecosystems, etc.).

Promoting the healthy functioning of ecosystems also directly improves ecosystem services (ES), which are defined as “the conditions and processes through which natural ecosystems, and the species that compose them, sustain and complete human life” (Daily et al. 1997); in short, “the set of ecosystem functions useful to man” (Kremen 2005). There are various benefits that individuals and society can obtain from ecosystems and they are organized in:

- Provisioning services, which are products obtained from ecosystems, for example, foods, freshwater, fiber, genetic resources, fuelwood, biochemical, etc.
- Regulating services, which are benefits obtained from ecosystem processes comprising climate and water regulation, pollination, water purification, etc.
- Cultural services, which are nonmaterial advantages obtained from ecosystems, comprising cultural heritage, recreation and ecotourism, sense of place, aesthetics, etc.

Biodiversity always plays a more or less significant role in all these services so that changes and/or losses of biodiversity affect the functionality in the production of ecosystem services that support various aspects of human well-being.

Ecosystem services are influenced by functional diversity in an ecosystem rather than by species diversity. Indeed, as formulated by McCann (2000), the stability of an ecosystem is related to its functional diversity that is able to provide diverse responses to environmental changes. For example,

if there is a competition for the same resource by two different species, it will result in the stabilization of ecosystem functions through the decline of one of the two species and the upper hand of the one that is able to do well under changed conditions, contributing to the maintenance of the ecosystem as a whole. Thus, the functional diversity in an ecosystem impacts ecological resilience (see), that is, the ability of ecosystems to resist stress and shock, to absorb disturbance, and to recover from disruptive change.

Many of the ecosystem services are linked with the ecosystem resilience; a decrease in resilience is expected to have, as a consequence, a decrease in ecosystem services, and, in this context, biodiversity can have a significant influence to ecosystem resilience (Myers 1996). Biodiversity, in fact, offers sustainability and resilience, especially in the poorest and most vulnerable countries where biodiversity has a safeguarding function of providing multiple sources of ecosystem services, for example, alternative options for food and/or other resources (MEA 2005). The loss of biodiversity also influences the sustainability and resilience of agricultural systems; in fact, the deletion of the entire functional groups of species in order to promote intensive agriculture has increasingly compromised the development of ecosystem services. Adopting agricultural systems capable of providing standard production (plant and animal) as well as ecological services that allow for the protection, conservation, and increase of biodiversity would make farmers less at risk for a loss of production and would make agricultural systems more resilient to environmental changes.

The first recognition of the value and commitment needed for the conservation of biological diversity was the Convention on Biological Diversity (CDB 1992), inspired by the world's growing commitment to sustainable development (see). For the first time in history, the Convention focused on the sustainable use of the components of biodiversity and on the benefits arising from the use of genetic resources.

Ten years after its establishment, political leaders at the 2002 World Summit on Sustainable Development agreed to “achieve by 2010 a significant reduction in the current rate of

biodiversity loss at global, regional and national levels as a contribution to poverty alleviation and to the benefit of all life on earth” (COP Decision 2002).

Globally, the 2010 biodiversity targets have not been met. The third edition of the Global Biodiversity Outlook (GBO-3) is one of the most significant documents produced during the year 2010, known as the International Year of Biodiversity. In the GBO-3, the probable, further, and rapid loss of biodiversity is reported with a consequent dramatic reduction of many essential services for human society. In response to this failure, at the tenth Conference of the Parties in Nagoya, in Japan, the CDB adopted a new strategic plan for biodiversity 2011–2020 including a vision for 2050 (CDB 2010). The plan provided for 20 ambitious targets, articulated in 56 indicators, collectively known as Aichi Biodiversity Targets, which have been the reference framework for the definition of global, national, and regional targets during this decade, in order to promote and take urgent and effective measures to stop biodiversity loss and ensure resilient ecosystems by 2020.

Summary

Often the term biodiversity is used as synonymous of species richness (the number of species present), although it also includes a wide range of biotic scales, from genetic variations within species to interactions between species and to the diversity of ecosystems. This is due to the fact that the changes generated by the variation in the richness and composition of species are the object where the research is most concentrated (Hooper et al. 2005). Variations in the components of the Earth's biodiversity have a strong impact on the properties and functions of ecosystems and on the goods and services they provide for the livelihood and well-being of humanity.

Synonyms

Biological diversity education; Education for biodiversity; Education for biological diversity; Education on biodiversity; Education on biological diversity

Definition

The biodiversity decline (see Biodiversity) relates to other urgent sustainable development topics (see Sustainable Development) like climate change (see Climate Change) and is one of the more alarming threats to the world of today (CBD 2000, 2020b; Erdelen 2014). Humans are completely dependent on other biological components for their survival, but humans are a threat to the planet's biodiversity. Yet, as a species with moral consciousness, humans are capable of learning and understanding how their activities affect the rest of nature, and how future biodiversity losses can be avoided. Therefore, biodiversity education (BE) is most important and is in need of development.

BE focuses on raising awareness on the necessity of sustaining a biodiverse planet (CEE 2013). This awareness includes understanding what biodiversity means, why it is important, how to safeguard it, and how to manage it. The aim is to encourage joint engagement and inclusion (see Inclusion) of various persons and groups in the work on biodiversity protection and preservation. *Protection* is a more instrumental approach to safeguard nature for human interests and *preserve* searches for a kinship with nature (Franco 2013). This means that the approach varies (see also Weak Sustainability and Strong Sustainability). Since biodiversity is more than a biological

concept, BE likewise relates to many other human domains, such as politics, the economy, social and cultural issues, legacy, and ethics (see Ethics and Ethics and Ethical Theories). BE is a lifelong process including people from the entire world and in the most various learning situations.

Introduction

The concept of biodiversity education comprises two words. While both these words are difficult to understand, they will first be separately interpreted with the education-related word “learning.” To begin with, biodiversity is a shortening of biological diversity, and it was coined in the 1980s. The Convention on Biological Diversity (CBD) defines the concept like this:

“Biological diversity” means the variability among living organisms from all sources including, inter alia, terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part: this includes diversity within species, between species and of ecosystems. (UN 1992, p. 9).

The core of the biodiversity concept from a biological view includes three levels: a genetic level, a species level, and an ecosystem level (see Ecology and Ecosystems). First, diversity at the genetic level implies the variety among individuals of the same species. Second, the species level is the diversity between species, which is the level that people usually relate to the biodiversity concept, and with it imply that a place with many species has a richer biodiversity (e.g., a forest with a more varied number of different tree species). Third, the ecosystem level includes the communities or habitats in which biological organisms interact with each other and with their physical environments (e.g., a lake, a forest, or a swamp). Besides these levels, conservation biologists emphasize the number of rare or endemic species in an area (endemic means that they are unique for a particular place), while urban biodiversity researchers mainly focus on the species richness in a particular spot (Szlavecz et al. 2011).

The *Convention on Biological Diversity* is the legal framework for the protection of biodiversity. The convention was signed by world leaders on the *UN Conference on Environment and Development* (UNCED) in Rio de Janeiro 1992, and it was ratified in 1993. Since then, nearly 200 countries have signed the agreement (CBD 2000). From the very beginning, lack of awareness and understanding of the urgency of biodiversity protection has been a vast obstacle to halt the loss of biodiversity efficiently. However, even in the first agreement in 1992, education and awareness raising play crucial roles (CBD 2000) (see Sustainability Education and Awareness). In the CBD strategic plan for biodiversity 2011–2020, including the so-called Aichi Biodiversity Targets from 2010, the very first target is: “By 2020, at the latest, people are aware of the values of biodiversity and the steps they can take to conserve and use it sustainably” (CBD 2020a). However, 10 years later, the report *Global Biodiversity Outlook 5* shows that this target has not been met (UNESCO/UNEP/CBD 2020). The *Update of the zero draft of the post-2020 global biodiversity framework* includes reformed targets. In the updated document, the first Aichi target has received a new and more precise formulation. Traditional knowledge has become visible, and people are specified by the decision-makers and general public: “By 2030, ensure that quality information, including traditional knowledge, is available to decision makers and public for the effective management of biodiversity through promoting awareness, education and research” (CBD 2020b, p. 7).

In addition to climate change, the loss of biodiversity is one of the main dilemmas needing to be solved, according to the United Nations Educational, Scientific and Cultural Organization (UNESCO) (2017) (see Biodiversity: Environment, and Biodiversity: Sustainability). Biodiversity is the basis of healthy ecosystems and sustainable human development and for all human life (see more in Freedman 2014). In addition, human activities are a major reason for the biodiversity loss. Therefore, education and learning on the issue of biodiversity are highly ranked

on the UNESCO's priority list. Education is a tool to gain knowledge, to shape new ways of viewing the world, and to create new practices.

The concept of biodiversity has a distinct definition (see the beginning of the introduction). However, the interpretation of this concept is not self-evident, especially in relation to education. This will become obvious in the next section. Before that, the word education needs to be clarified. "Education" is a usual word that entails schooling, instruction, tutoring, coaching, learning, and various experiences (Jeronen 2012; Wolff 2011). Education takes place in numerous situations and includes targets of many kinds. The site for education can be a preschool, elementary school, or higher education institution (formal education), or it can take place in some other arranged situation outside the educational system (non-formal education). Education also happens in more or less usual (unplanned) daily life situations (informal education). Sometimes, the educational processes involve people in the roles of teachers and students, but learning can also take place without a teacher. Education is much more than a transmission of information from one transmitter (teacher, computer program, book, etc.) to a person. Concepts like communication, illumination, information, and participation (see Participation) are thus sometimes indistinct from education or are at least overlapping.

Similarly, the education-related word "learning" can be interpreted variously. Learning takes place in many completely different circumstances and in various contexts (see Sewell and Newman 2014; Wolff 2011). Yet, education does not always advance to learning. Many elements affect the learning situations, and for learning to happen, these elements need to correlate. The learning environment (physical and social), the learners' and teachers' attitudes and experiences, not to talk about wider political frameworks and social norms, all influence how people learn. The education can aim at a "transmission" of traditions and norms, or a "transformation" (cf. Transformative Learning) aimed at worldview transformation and a change of thinking or practice, even a societal change. When it comes to BE,

the concepts education and learning have to be interpreted in various ways. This is a challenge, but also an opportunity, since the development options in the field already exist. This text brings forward ideas from the multifaceted field of BE.

Biodiversity: A Complex and Ethically Challenging Educational Issue

Since biodiversity is a complex issue, it calls for actions of many kinds. Even if many interesting projects are going on in relation to BE, many difficulties are involved in the topic of biodiversity. Accordingly, it is necessary to reflect on some of these difficulties, since they are all obvious in BE, and must be considered. The first problem is ethical and relates to humans' position in the natural world and their rights and obligations in connection to other species. Other problems relate to location, social and economic matters, and, finally yet importantly, time. In addition to its relational feature, the biodiversity issue is interdisciplinary.

Ethical Problems

When discussing biodiversity as well as BE, it is usual to stress that humans need nature now as well as in the future and that specific species might be beneficial in hitherto unknown ways as medicine, building materials, or for other scientific reasons.

'Biological resources' includes genetic resources, organisms or parts thereof, populations, or any other biotic component of ecosystems with actual or potential use or value for humanity. (UN 1992, p. 9)

Beside biological resources, the concept "ecosystem service" is common, including all the benefits humans have from nature (see Wägele 2014; Erdelen 2014). However, this anthropocentric view neglects that nature might have an intrinsic value and be valuable for its own sake (Sturma 2014). On the other hand, if nature has an intrinsic value, humans might not be the ones to decide which parts of the biological domain that have a right to live. Still, humans are a species capable of

making such a decision. If every species is treated equally, insects who destroy crops that humans or domestic animals feed on, or those who transmit diseases, are all allowed to exist. From an eco-centric view, in which nature has an intrinsic value, nature must be preserved, while an anthropocentric view asks for conservation of nature (Van Dyke 2014). However, questions remain about what nature needs protection and from what it has to be preserved. Compromises between these perspectives are often the only realistic directions.

Another ethical problem is what nature is. In one way or another, most land on Earth is affected by humans. In addition, most humans live in urban environments, with nature areas composed of many species from other geographical zones and continents far away. To draw a line between what is natural and worthy of protection is then all but easy.

Even if the genetic, species, and ecosystem levels call for different approaches, these levels are often interconnected. In addition, they are associated with human matters like economics and politics (Spash and Aslaksen 2015) and are influenced by human traditions, values, and emotions. When humans make decisions based on which genes of a special species are economically best to invest in, they easily neglect subspecies less suitable for cultivating or breeding, and genetic diversity decreases. In the same way, pragmatic values of other kinds may lead to a decline in diversity at the species and ecosystem levels. Even abstract aims like historical, aesthetic, and symbolic values influence decisions and choices.

When it comes to the educational implementation of the biodiversity issue, many of the political documents mention behavioral change as a purposeful aim of BE (see CE 1995; CEE 2013; UNESCO/UNEP/CBD 2020). This is also an ethical problem (see ► “Ethics of Sustainability Education”). If BE strives to change other people toward specific norms, it becomes reminiscent of indoctrination and is far from transformative learning (Wolff 2011). Therefore, awareness of this risk and negotiations on it is a necessary part of BE development.

Locational Problems

Other BE problems relate to geography and locations. The biodiversity on planet Earth is unevenly distributed; some areas have much greater diversity than others do, and the richest areas are called *hotspots* (Van Dyke 2014). A rich biodiversity occurs on areas with apposite biotic factors (non-biological factors like climate, soil, etc.), but these areas may be economically weaker than areas with much poorer biodiversity.

Nature does not follow human boundaries. Rivers and other bodies of water traverse political borders. Some species and thus genetic material continually change residence and location (Kühl-Stenzel 2014). Among them are migrating birds that spend their lives in several countries. Humans also move around substances. Biological raw material, such as nutrition plants, may grow in one part of the world and be transported for refining in another and again transported for sale in a third. This makes the same plant dependent on politics, economics, and legislation in several states. Even if the transportation of sensitive biological material like blood, tissue, DNA, and microorganisms is regulated by international laws, these kinds of moving are always risky (damage, crimes, etc.) and may be a danger to someone.

Social and Economic Problems

When studying biodiversity, the social and economic aspects cannot be avoided (Spash and Aslaksen 2015). The biodiversity topic is strongly related to the well-being of humans, to equality, and gender, as well as to trade and employment questions. Biodiversity protection as such generates jobs, but biodiversity is also linked to more traditional livelihoods like fishery, agriculture, forestry, and water management.

Biodiversity relates to cultures and traditions in specific areas, and its protection may conflict with the rights of vulnerable groups and indigenous people (Bubna-Litic 2014). Likewise, the protection of biodiversity may be in the interest of local people, but not acknowledged by international politics or by transnational trade and economic organizations.

According to the Aichi Biodiversity Targets, among the major challenges for the Decade on Biodiversity was poverty, loss of livelihood, water scarcity, desertification, access and benefit sharing of genetic resources, and erosion of traditional, indigenous knowledge and values (CEE 2013).

Development and Time-Related Problems

A further set of problems relate to development and time (Wolff and Skarstein 2020). Humans' use of nature has a history, a present day, and a future. How to relate to all these time dimensions in education connects to cultural traditions and social circumstances but also to technology development and economics. Local and international agencies and citizens need to have the opportunity to participate and have their say in the biodiversity debate and be a target for educational endeavors.

A Quest for a Multiple Approach

Finally, BE reflects complexness in many ways. The biodiversity dilemmas obviously call for broad perspectives, knowledge, and skills from various disciplines (see ► [“Transdisciplinary Learning”](#)), employment of several educational methods, and inclusion of multiple groups (Erdelen 2014). It is not enough to deliver knowledge from a strictly scientific or biological angle. A wider examination might bring necessary restrictions to the surface — at least theoretically.

Critical examination and revisions which meet the standards of ethical justification will lead to normative restrictions on the options of human activities. These restrictions will, at least to some extent, suggest a withdrawal from certain habitats. (Sturma 2014, p. 130.)

The Tasks of Biodiversity Education

BE appeared on the educational agenda at the beginning of the 1990s. Important partners in the development of BE have been the CBD, UNESCO, UNEP (United Nations Environment Programme), IUCN (International Union on Conservation of Nature), and WWF (Worldwide

Fund). Yet, there have been earlier attempts that also could be called BE. An example of that are the books by Maria Merian (born 1647), who skillfully combined art and biology describing insect species (mainly butterflies) and plants in a clear pedagogical way (see, e.g., Sidman 2018).

Biodiversity was a major topic for the *European Nature Conservation Year 1995*. The Council of Europe (CE) report from this special year highlights climate change as a major sign of how humans mistreat planet Earth (CE 1995). Therefore, the report emphasizes actions that could limit the damage and restore the environment.

Preserving the planet is the most important political aspect of *European Nature Conservation Year*, and society must be called upon to pull together as a whole. We must be more mindful of our local environmental situation. (CE 1995, p. 3.)

The CE report shows that many countries in Europe worked with BE in 1995. The activities included conferences, seminars, courses, and research days; production of material, such as booklets, videos, and songs; outdoor education, rehabilitation of nature areas, setting up nature trails, and planting hedges; and arranging exhibitions. BE was also the topic of the IUCN's *Commission on Education and Communication's* regional organization *European Committee for Environmental Education's* workshops 1995 and 1996. These workshops resulted in a publication on biodiversity education and communication discussing both biodiversity as a concept and its educational implications. The practical part of the publication includes topics like how to influence decision-makers and school policy, biodiversity in formal education, teacher training, communication and media, rural and urban BE, and the use of drama methods in BE (IUCN 1998).

In 2002, the CBD adopted the global initiative *Communication, Education and Public Awareness* (CEPA), with the UNESCO as the key partner (CEE 2013). Despite the ambitious strategy of international cooperation and inclusion of BE in education on various levels, the aims of this initiative were not met. Even if governments showed understanding, they were not willing to provide

resources. On national levels, there was a lack of knowledge management (see Knowledge Management), political willingness, and expertise in relation to BE. Subsequently, the *International Year of Biodiversity 2010* especially stressed the role of education and so did the program for the *UN Decade on Biodiversity 2011–2020*. Yet, who is BE actually for, and how could it be implemented?

The Target Groups of Biodiversity Education

BE starts from the smallest children at home, in daycare, and in preschools; continues through elementary, secondary, vocational, and higher education; and continues to workplace training and other professional instruction. BE is also a part of leisure time courses and activities. Through BE, it is possible to initiate learning conditions activating rural as well as urban citizens, indigenous people as well as officials, politicians, researchers, and other stakeholders in mutual dialogues and activities.

The campaign target audiences for the *European Nature Conservation Year 1995* were municipal, regional, and national authorities; people depending on the natural environment for work or leisure pursuits (e.g., farmers, foresters, fishers, or hunters); landscape users (tourists, property developers, etc.); and young people. The last-mentioned group was especially underscored (CE 1995). These target groups are still relevant in 2021. Yet, the list has developed and the specification of the target groups becomes increasingly more distinct.

With support from the UNESCO and in collaboration with the CBD, the *Centre for Environment Education* (CEE) in India prepared a strategy intended to facilitate the promotion of the 19 *Aichi Biodiversity Targets*. This strategy aimed at integrating the goals of *Education for Sustainable Development* (ESD), especially the experience from the *UN Decade of Education for Sustainable Development* (2015–2014) (see Decade of Education for Sustainable Development, and United Nations Decade of Education

for Sustainable Development), with the goals of the CBD (CEE 2013). The targets listed by the CEE are governments (officers and decision-makers on several levels), communities, NGOs (non-governmental organizations, see NGOs and Sustainability and NGOs) and CBOs (community-based organizations), business groups (public and private), media, general public, researchers, teachers, students, and youth (CEE 2013). However, the strategy overlooks the children under 6 years, even if they are included already in the IUCN publication of 1998.

Even if the CEE (2013) stresses that all citizens need BE, the strategy recommends that the planning of a specific action or learning project starts from an identification of the key stakeholders. In addition, the document emphasizes the importance of understanding the background of the key groups. This includes understanding for their socioeconomic and cultural backgrounds, their basic values, their knowledge levels, and how they are used to manage biodiversity. Thus, the BE can build on what these target groups need, acknowledge their preunderstanding and previous skills, and create education based on this information. When the educational planning starts from the premise that all stakeholders have something to bring forward, the communication and learning approach becomes reciprocal.

Biodiversity Education in Early Childhood and School Age

Spontaneously, BE might first be taught of as education taking place in schools. Yet, it is not enough that students in school age learn about biodiversity. The issue is broad and has to be an ingredient in education outside school as well. However, with a good start at an early age, the interest has already been awakened. This practical part of the text starts with a description of BE in early childhood, and in schools, and continues with various adult groups.

Biodiversity Education in Early Childhood

In early childhood settings, BE is a part of the daily activities and communication. Yet,

childhood is not restricted to special places with purposeful education. Interviews with older children and adults have approved the importance of authentic experiences of nature as a child. Early frequent experiences of organisms in their habitats generate an interest and “open the children’s eyes” for natural phenomena like biodiversity (Wolff and Skarstein 2020). With small children, communication is part of the exploration. Together, adults and children experience new phenomena outdoors and spend time finding out what happens around them by carefully listening and watching. Indoors, the studies continue with the help of pictures and books and by drawing, singing, and pondering. Play and dialogues are part of the learning processes, and the choice of pedagogical strategies is significant (Edwards and Cutter-Mackenzie 2013). In addition, the adults’ way of talking about biodiversity-related issues makes a difference. At an early age, children can learn what living and non-living material is, adapt concepts and species names, and discuss ethical problems related to how to treat other creatures.

Biodiversity Education in Schools

Like in the early years, authentic learning is also a benefit for children of school age, and a combination of indoor and outdoor activities is being used to promote scientific literacy, as well as care and responsibility (see Responsibility). The means and activities depend on the age, but below are examples of methods to modify these according to the group in question (Wolff 1998; Yli-Panula et al. 2018). Interdisciplinary approaches are beneficial, when appropriate, since the biodiversity topic includes many fields of knowledge. Besides teacher-led instruction, problem-based learning, phenomenon-based learning (see Phenomenon Based Learning), and other student-centered approaches suit BE well (Jeronen et al. 2017). Experimental learning, role-play, and discussions are parts of BE. The students need a critical analyzing skill, ability to evaluate their own lifestyle, and ability to understand casual relationships. Learning how to use technology and media sensibly in biodiversity inquiries (Yli-Panula et al. 2019)

and gain insight in both how to influence decisions and how to envision the future also belongs to a critical learning approach (Wolff 1998, 2011). The foundation of BE is biology (ecological interdependences, the role of microbes, climate factors, human diversity and adaptability, genetic diversity and engineering, etc.). Yet BE relates to history, geography, chemistry, physics, mathematics, language, art, and social studies, among other subjects. The students need to become familiar with politics and nature management, as well as biodiversity-related research.

Outdoor BE includes sense experiences, hands-on learning, training in observing, examining, and “reading nature” (Jeronen et al. 2017). Aesthetic experiences, drama, games, and practical activities like gardening, are also beneficial (Wolff 1998). The utensils can be simple outdoor equipment as well as cameras and other digital tools. Partnership with other local schools and schools in other regions and parts of the world extends the biodiversity perspectives (see Skarstein and Wolff 2020). Collaboration with other local interest groups, like the community’s decision-makers or officials, also enriches the experiences. Metacognition, analyzing thinking skills, synthesis making, and evaluations support the higher-order thinking and develop best in meaningful real activities (see Jeronen et al. 2017 and the examples of BE for adult groups in the next section). Finally, the role of species knowledge and identification and naming of local species and their habitats in combination with authentic experiences is a core in BE in schools (see Jeronen et al. 2017). Nevertheless, underpinning values guide the learning process. It is, therefore, a challenge to develop educational methods that combine cognitive outcomes (through scientific knowledge), personal experiences (through outdoor activities), and value-related issues (through reflections and debates). This is necessary to activate the students’ interest and encourage them to a sustainability envisioning and to start acting responsibly on behalf of a more sustainable and biodiverse future (Sjöblom and Wolff 2017).

Examples on Biodiversity Education for Various Adult Groups

In schools and other educational institutions, BE can be included in the teaching subjects as a natural part of the content and methods in a combination of theories and practice. In adult learning, BE is often performed in the form of multi-stakeholder projects. After finishing school, engagement in shorter biodiversity activities might be the only option. Continuous BE might sound superior to project-based learning, but what is best depends on the target and the situation. Next are examples of BE initiatives from various adult education contexts in a number of countries.

Collaborative Learning About Alien and Invasive Species

A fundament of biodiversity conservation and land management worldwide is the controlling of alien and invasive species. From earlier focusing merely on the biological dimensions of the problem, the emphasis has now turned to the human dimensions including social and economic aspects (Davies et al. 2016). Education plays a crucial role in tackling the invasive species problem. In South Africa, the biological invasion is a challenge for education that stretches from rural communities to shipping companies (Davies et al. 2016). This has been tackled through education that includes on-the-job training as well as advanced degree training for people already in service. Likewise, training of researchers from various disciplines is a growing field. Researchers cooperate with landowners and lobby groups to develop management strategies for the so-called “conflict species,” a concept that implies that a species initially introduced for its benefit have become problematic and invasive (Davies et al. 2016). In addition, stakeholder workshops offer learning environments, in which people with different interests and initial knowledge discuss and change experience and learn from each other.

Learning About Endemic Insect Species

A BE project in the Azores (an island in the Atlantic belonging to Portugal) focused on endemic insect species (Amorim et al. 2016).

Since the Azores have a large endemic insect fauna, an aim was to raise attention about the life of insects and their ecological roles as pollinators, decomposers, and regulators of other organism populations. The communication method of this project was a large outdoor exhibition (street exhibition) and a web contest. Since some insects lacked common names, the audience on the Internet was asked to name them. The result from this project was learning how it was necessary to know the target and to establish trust between communicators and target groups. A BE process demands increasingly mutual accommodation and modification and a multidisciplinary approach. Evaluation has to take place continuously and be sensitive to peoples’ reactions. This project also showed that aesthetic values and emotions influence the appreciation of organisms, and therefore, insects are a more challenging BE topic than, for example, birds.

Citizen Science in Urban Landscapes

Urban areas and city backyards are good places for citizen science programs. Studying biodiversity and developing BE in urban areas is not only an issue for biology but also for social science. The urban ecosystems have special features. In urban areas, the species composition is heterogeneous and different than in nature areas more typical for the actual climate zone. In addition, the species’ genetic adaption is fast, and the impact of humans on ecosystems is big. Citizen science programs, in which citizens and scientist collaborate, have taken place in the UK, Canada, Baltimore, Germany, and the USA, for instance (Szlavec et al. 2011). The aim is to attract various groups, like taxonomists, park managers, and the public (citizens including families and school classes), for joint projects on the search and observation of particular species, revitalizing of neighborhoods, or installing new management principles. The participants in these projects have shown interest in the projects and have been willing to help the researchers. Still there is a need for studies focusing on issues like the mechanism between human socioeconomic factors and species diversity, the effect of humans on prey populations, BE’s long-term influence on

decision-making, what kind of diversity humans value, and many other questions that could become citizen-scientist partnership projects.

Involving Local Stakeholders in Biodiversity Conservation

A project in Mexico strived to unite researchers, NGO members, and local stakeholders in the topic of how sociocultural elements influence the efficiency of conservation initiatives (Ruiz-Mallén 2016). Democracy, mutual understanding, and learning in dialogue about resource management were the core in this BE project. The approach was interdisciplinary and based on many interactive methods, such as local engagement in conservation initiatives and management procedures. An interesting finding was the significance of traditional knowledge and the history of the community in enforcing biodiversity protection. The involvement of local people in dialogues about their relationship with the surrounding nature in past, present, and future perspectives produced new knowledge and enhanced learning both for the society and for the researchers.

Student Teachers Learning Species

Teachers need knowledge and skills to have confidence to engage children and students in biodiversity issues. Research on training of teachers in species knowledge has been going on for many years in the Nordic countries. In a collaboration project between Finland and Norway, early childhood student teachers attending university courses learned to identify and know about species (Wolff and Skarstein 2020). During the Finnish course that was based on a similar course in Norway, the students had to identify 95 species (birds, mammals, reptiles, amphibians, and plants). Part of the course took place outdoors in various settings, in a botanical garden, on a farm, in a nature reserve, and in an urban area. The quantitative result was very good, as was the qualitative result. The species knowledge improved remarkably. Another result was that the learning was joyful and rewarding for the students, and they developed nature observation skills they regarded useful in their coming work.

The results correspond with studies on how primary and secondary student teachers learn about biodiversity. Field studies in authentic environments evidently promote learning (Jeronen et al. 2017; Palmberg et al. 2019). When the students confront living organisms in their natural habitats, both the students' knowledge and curiosity grow. In addition, research from the Nordic countries has shown that early childhood student teachers as well as primary and secondary student teachers regard biodiversity knowledge, skills, and interests as being important in promoting sustainability (Palmberg et al. 2018; Skarstein and Skarstein 2020; Wolff and Skarstein 2020).

Multicountry e-Learning Courses

The final example is train-the-trainer courses including both e-learning and intensive phases (Argiolas et al. 2016). The participants came from four regions, southeast Europe, southeast Africa, north and west Africa, and from twenty-two countries. The topic was biosafety, biosecurity, and bio risk management related to biological substances, and the target was academic experts in this field. The training was tailored and focused both on collaboration and on local needs. Since the platform was open after the courses had ended, the content could be further developed and translated into local languages and particular needs. This is an example of how multiple perspectives and experiences can become a joint BE development project.

Summary

Many BE projects take place around the world both in schools and in other contexts. To learn from these projects and to develop new strategies, continual and purposeful evaluations are crucial. Educational development builds on the willingness to share and learn from earlier experiences (also from failures) and to continue searching for better methods in cooperation between education practitioners, students, researchers, managers, decision makers, NGO members, and others.

BE is not only a way for knowledge delivery and skills training. Nevertheless, it has to be

clearly included in the curricula (see Sustainability in Curricula: Sustainability Education). It may bring about critical learning and initiate the process of becoming and enable a joint transformation of the world. Consequently, the development of BE is simultaneously a way to develop more appropriate education for the world of today and in the future. Finally, available resources, adequate investments, and purposeful actions will show if BE receives the status in educational frameworks that the current situation of ever faster-growing biodiversity loss demands. Success requires a well-functioning and dynamic education system, which is open to flexibility. Introducing new urgent learning topics like BE is not only a question about protecting a diverse nature, but also about social and gender equality, fair distribution of goods, availability of clean drinking water, and food for all. Biodiversity awareness is built up in critical dialogues and interactions, in which even diametrically opposed perspectives are allowed to respectfully confront each other and have a voice.

The complexity of the environment inaugurates a new pedagogy of a dialogic and subjective reappropriation of knowledge, moved by values, interests and utopias, a confluence of different forms of knowledge in permanent diversification and differentiation. (Setti and Azeiteiro 2016, p. 237).

[Biological diversity](#)

Definition/Description

Biodiversity is the shortened form of two words “biological” and “diversity.” Since the Convention on Biological Diversity was adopted at the Rio “Earth Summit” in 1992 (UNCED 1993), biodiversity has been discussed on three dimensions: ecosystems, species, and genes. Ecosystem

diversity relates to the variety of habitats, biotic communities, ecological processes, and the diversity within ecosystems. An ecosystem is (UN 1992): “a dynamic complex of plant, animal, and micro-organism communities and their non-living environment interacting as a functional unit.” For a business, an ecosystem perspective focuses on where a company operates within the ecological landscape (IUCN 2002).

Species diversity refers to the variety of species within a region. The “biological species definition” or the “biological species concept” is based on Ernst Mayr’s definition (Mayr 1942): “Species are groups of actually or potentially interbreeding natural populations, which are reproductively isolated from other such groups.” They provide ecosystem services recycling wastes, purifying water, driving biogeochemical cycles, maintaining an aerobic atmosphere, regulating climate, and generating soil fertility (IUCN 2002).

Genetic diversity refers to the variation of genes within species. Genetic material is (UN 1992): “any material of plant, animal, microbial or other origin containing functional units of heredity.” The corporate sector plays a dominant role in the commercial use of it (IUCN 2002). Biodiversity emphasizes the interrelated nature of the living world changing constantly by evolution. It is of value for cultural and recreational purposes.

Introduction

“Biodiversity,” or “biological diversity,” is fundamental for continuous life on Earth. It includes a range of ecosystems and habitats. An ecosystem is a community made up of living organisms and nonliving components such as air, water, and mineral soil (Schulze et al. 2005). Natural habitats include land and water areas characterized by certain environmental conditions and by the plant and animal species typical of such areas (Ministry of Environment and Finnish Environment Institute 2016) (Figs. 1, 2, and 3). A species’ habitat is those places where a species can find food, shelter, protection, and mates for reproduction.

Waste and emissions produced by human beings have an impact on ecosystems and habitats from the local level to the global one. For this reason, people depend on so-called ecosystem

services. The Millennium Assessment (MA) defines ecosystem services as “the benefits people obtain from ecosystems. These include provisioning...regulating services...cultural services...and supporting services” (MEA 2005, p. V). Biodiversity has been seen to be a contributor to ecosystem services, to be an ecosystem service itself, and to be a product of some ecosystem services (Gaston and Spicer 2004; MEA 2003). The ecosystem services have provisioning such as food and water, cultural such as for recreation, and supportive characters like nutrient cycles. They also play an important role for the quality of life in a city regulating a city’s climate,

filtering emissions and protecting a city against flooding (UN Environment 2018). Biodiversity is therefore essential for human well-being, health, and resilience (Sala et al. 2009), as well as for human social and economic development (UNCED 1993; UNESCO 2014).

Key Issues

“Biodiversity” refers to the total variability of life on Earth (Heywood and Watson 1995, p. 5). It includes both variations at taxonomic levels (species, genus, family, order, class, phylum, kingdom, and domain) (Ruggiero et al. 2015; Woese et al. 1990) and at the genetic level, as well as variation in ecological functions (Butchart et al. 2010) such as those of pollinators and seed dispersers. Species are divided into bacteria, archaea, protozoa, chromista, plants, fungi, and animals

(Ruggiero et al. 2015). Many species are characterized by their unique adaptations to the local environment and special climatic conditions. Conservation of biodiversity is often conceptualized through the extinction of species, threatened species, and biodiversity loss. When reflecting the interaction of ecological, economic, and social issues, the biodiversity dimensions are important parameters of sustainability (Kassas 2002; Van Weelie and Wals 2002; WCED 1987). For example, tropical rainforests are not only important for living plants and animals but also important for people’s living environment and for preserving their local and regional cultures. Each ecosystem differs in detail from every other and changes over time. Examples of ecosystems are forests, grasslands, and rivers. All ecosystems are facing problems of pollution, climate change, and urbanization, resulting in biodiversity loss (Fig. 4). For terrestrial ecosystems, further threats

Biodiversity: Environment,

Fig. 4 Factors affecting biodiversity (Holdgate 1979; MEA 2003; McKinney 2002; Niemelä 1999; Pickett et al. 2001; CSR 2011; Earthwatch 2018)

include air pollution, soil degradation, and deforestation. For aquatic ecosystems, threats include also unsustainable exploitation of marine resources (for example overfishing of certain species), marine pollution, microplastics pollution, water pollution, and building on coastal areas (Alexander and Fairbridge 1999).

Holdgate (1979, p. 17) defined environmental pollution as: “the introduction by man into the environment of substances or energy liable to cause hazards to human health, harm to living resources and ecological systems, damage to structures or amenity, or interference with legitimate uses of environment.” The definition can be applied to all types of pollution ranging from physical to economic, political, social, and religious. Over the past decades, various sources of pollution have been identified that altered the composition of water, air, and soil of the environment. The substances that cause pollution are known as pollutants. According to Rai (2016), a pollutant can be any chemical (toxic metal, radionuclides, organophosphorus compounds, gases) or geochemical substance (dust, sediment), biological organism or product, or physical substance (heat, radiation, sound wave) that is released intentionally or inadvertently by man into the environment with actual or potential adverse, harmful, unpleasant, or inconvenient effects. Undesirable effects affecting human beings may be direct or indirect, being mediated via climate change or resource organisms.

Climate change is likely to become one of the most significant drivers of biodiversity loss by the end of the century (MEA 2003). It is already forcing biodiversity to adapt either through shifting habitat, changing life cycles, or the development of new physical traits. Environmental change causes changes in the distribution of single species including the potential increase of the immigration of non-native species (Hoffman and Courchamp 2016). Such migrations might result in new species-species interactions like pollinator shifts, new host-parasite systems, and hybridization after new contact. Detrimental impacts of non-native species on native biota have occurred through competition, predation, herbivory, habitat alteration, disease, and genetic effects. There are

potential effects on genetic biodiversity as well as species biodiversity (Manchester and Bullock 2000).

Urbanization has impacts on biodiversity transforming the ecology of an area. Such transformation can include, for example, the alteration of habitats, such as the loss and fragmentation of natural vegetation, and the creation of novel habitat types (McKinney 2002; Niemelä 1999; Pickett et al. 2001). Habitat fragmentation has confined many species to relatively small areas within their previous ranges, resulting in reduced genetic variability (UN 2018). The ecosystem services (e.g., air, water, and climate regulation, pollination) and other resource flows (e.g., reduction in net primary production, increase in regional temperature, and degradation of air and water quality) can also change (Henry and Dicks 1987; Rebele 1994) as well as disturbance frequencies (Rebele 1994). In addition, there can be disruption of species occurrence and abundance patterns, commonly including the local extinction of many species that are habitat specialists, require large habitat patches, utilize the interiors rather than the edges of patches, or are associated with complex vegetation structures (Chace and Walsh 2006; McKinney 2002; Pickett et al. 2001).

Losing biodiversity means losing ecosystem processes. Ecosystems are significantly influenced by multiple evolutionary responses to environmental change that act on species' relationships with other species. These multispecies interactions range from different symbiotic interactions like mutualism to true coevolution (Lin et al. 2017). Conservation of natural terrestrial, freshwater, and marine ecosystems and restoration of degraded ecosystems including their species and genetic diversity is essential because ecosystems play a key role in the global carbon cycle and in adapting to climate change and because they provide ecosystem services that are essential for human well-being.

Biodiversity can support efforts to reduce the negative effects of climate change. Conserved or restored habitats can remove carbon dioxide from the atmosphere, thus helping to address climate change by storing carbon, for example, reducing

emissions from deforestation and forest degradation. Moreover, conserving in-tact ecosystems, such as mangroves, for example, can help reduce the disastrous impacts of climate change such as flooding and storm surges. It may modify the prevailing ecological conditions, affecting the recolonization potential and modifying the extent and trajectory of ecosystems' recovery process after pressure intensity has been reduced (Cf. Fuller et al. 2010). The impact of climate changes represents an additional constraint for restoration programs or in preventing ecosystems deterioration.

The biosphere is itself the product of life on Earth. The composition of the atmosphere and soil, the cycling of elements through air and waterways, and other ecological assets are all the result of living processes and they all are maintained and replenished by living ecosystems. The human species, while buffered against environmental immediacies by culture and technology, is ultimately fully dependent on the flow of ecosystem services (MEA 2003). Several studies have emphasized knowledge of place as an important driver of local action and planning initiatives (Davenport and Anderson 2005; Gobster et al. 2007; Larson et al. 2013; Williams and Stewart 1998).

To promote the well-being of nature and people, corporations can take into account in their Biodiversity Action Plans (CSR 2011; Earthwatch 2018), for example:

- Assessment of the risks and impacts associated with biodiversity in relation to sustainable use of biodiversity
- Assessment of the risks and impacts on biodiversity and prioritize actions
- The plant of a management schedule that details the appropriate actions and a monitoring program to enable the effects on biodiversity to be assessed
- Realistic targets for the implementation of a company biodiversity action plan
- The evaluation of the biodiversity action plan on a regular basis
- Communication concerning company biodiversity initiatives with staff and external stakeholders for equitable benefit sharing and strengthening of management, evaluation and reporting systems, and for identification of new opportunities

The financial values assigned to biodiversity depend strongly on the purposes of valuation. Utilitarian benefits include the values of presently marketed and presently unexploited nature products, and the monetary value of environmental benefits. Nonmonetary values of nature are also essential components of decision-making (cf. Kelemen et al. 2016). Decisions regarding creation and management of various kinds of reserves are likely to be key factors in determining the long-term future of biodiversity.

Summary

Biodiversity means the variability among living organisms from all ecosystems and habitats. Many species are characterized by their unique adaptations to the local environment and special climatic conditions. Climate change is one of the most significant drivers of biodiversity loss. Environmental change causes changes in the distribution of single species and the alteration of habitats. Ecosystems play a key role in the global carbon cycle and in adapting to climate change. Thus losing biodiversity means losing ecosystem processes. In addition, conservation of different ecosystems and restoration of degraded ecosystems including their species and genetic diversity is essential, because biodiversity has been seen to be a contributor to ecosystem services, to be an ecosystem service itself, and to be a product of some ecosystem services. Not only utilitarian benefit but also nonmonetary values of nature are key factors in decision-making regarding creation and management of various kinds of reserves. How the utilitarian benefit and the nonmonetary values of nature are taken into account will determine the future development of biodiversity and future of human beings in the short and long term.

Synonyms

Biological diversity; Natural diversity

Definition/Description

The scientific concept of biodiversity refers to richness in variation among all living organisms at three levels: ecosystem diversity, species diversity, and genetic diversity (WCED 1987). According to WCED (1987), ecosystem diversity means variety of habitats, living communities, and ecological processes. Species diversity includes the number of species and number of individuals of each species in a particular location. Genetic diversity again means richness of the variety and range of genes within and between populations of organisms (WCED 1987).

In addition to these three dimensions, the fourth dimension is also mentioned. It is human cultural diversity (Chivian 2002; Heywood and Watson 1995). Cultural diversity means the

ethical, spiritual, and cultural values (Callicott et al. 1999), driving forces and human influences, as well as the measures for the conservation and sustainable use of biodiversity (Heywood and Watson 1995). All four dimensions are important parameters of sustainability, when reflecting the interaction of ecological, social, and economic issues (WCED 1987; Van Weelie and Wals 1999; Kassas 2002).

Conservation of biodiversity is often conceptualized through the extinction of species, threatened species, and biodiversity loss (Butchart et al. 2010). Biodiversity is fundamental for continuous life on Earth. It is also essential for human health and resilience (Sala et al. 2009), as well as for social and economic development (UNCED 1993; UNESCO 2014).

nitrogen deposition all result biodiversity losses (Sala et al. 2009). The Convention on Biological Diversity at the Rio Earth Summit stated that biodiversity is “a common concern of human-kind” and that it should be “an integral part of the sustainable development process” (UN 1992, p. 3). The convention also recognized that ecosystems, species, and genes can be used for the benefit of humans. However, this should be done in a way and at a rate that does not lead to the long-term decline of biodiversity. Later on, biodiversity has been seen as one of the major pathways to sustainability (Gayford 2000) and the protection of biodiversity as one of the basic roads to sustainability (Dikmenli 2010).

Key Issues

Introduction

Human actions and their effects on environment change biodiversity at both local and global levels. Human-driven climate change, habitat destruction, invasive species introductions, and

Biodiversity is usually considered at three different levels: ecosystem diversity, species diversity, and genetic diversity (UN 1992) (Fig. 1).

Ecosystem diversity relates to the variety of habitats, biotic communities, and ecological processes, as well as the diversity present within

Biodiversity: Sustainability,
Fig. 1 Biodiversity dimensions (UN 1992; Chivian 2002; Heywood and Watson 1995)

ecosystems in terms of habitat differences and the variety of ecological processes. Species diversity refers to the variety of living species (Figs. 2 and 3) (UN 1992). Genetic diversity includes (UN 1992): “any material of plant, animal, microbial or other origin containing functional units of heredity.” Biodiversity increases when new genetic variation is produced, a new species evolves, or a novel ecosystem forms, and it decreases when the genetic variation within a species decreases, a species becomes extinct or an ecosystem is lost or degraded (Australian Government 2007). The corporate sector plays a dominant role in the commercial use of biodiversity (IUCN 2002). The fourth dimension, human

cultural diversity (Chivian 2002; Heywood and Watson 1995) recognizes the important role of sociological, ethical, religious, and ethno-biological values in human activities (Heywood and Watson 1995). Biodiversity emphasizes the inter-related nature of the living world – including human being – that is changing constantly through evolution, therefore, the role played by humanity in the interrelation is significant (Yli-Panula et al. 2018).

The most fundamental needs and requirements of human society are supported by biodiversity. Essential services provided to the society include material goods, such as medicines, food, and fibers, as well as various services required to underpin ecological functions, such as flood control, climate regulation, nutrient cycling, maintaining hydrological cycles, cleaning water and air, soil formation and soil storage (Millennium Ecosystem Assessment 2005), pollination and pest control, and carbon sequestration and storage (Barton and Pretty 2010). All of these are interwoven with cultural, social, aesthetic, and ethical values (Swift et al. 2004), as well as emotional and recreational nature experiences (Braun and Dierkes 2017). Biodiversity is the basis of numerous ecosystem services that keep the natural environment alive, ranging from maintaining watersheds that provide fresh water to pollination and nutrient cycles, and the maintenance of clean air and atmospheric gases. The interdependence between humanity and biodiversity is critical for all peoples, because all communities ultimately depend on biodiversity services and resources. Some people lead lifestyles that are more directly dependent on biodiversity than others, their culture, history, and identity being intimately associated with the natural environment and its systems. Different cultures and peoples perceive and value biodiversity in different ways as a consequence of their distinct heritages and experiences. But even though many people’s dependence on biodiversity has become less tangible and apparent, it remains critically important for all communities (Australian Government 2007). The preservation of biodiversity forms the core of sustainability (Gayford 2000), and the protection of

Biodiversity: Sustainability, Fig. 2 Polypore. (Photo: E. Jeronen)

Biodiversity: Sustainability, Fig. 3 Whooper swan. (Photo: M. Kortessluoma)

biodiversity is a prerequisite for sustainable development (Dikmenli 2010).

Biological diversity and its components have the intrinsic value and also the ecological, genetic, social, economic, scientific, educational, cultural, recreational, and aesthetic values (UN 1992). Biodiversity values transcend boundaries imposed by man such as watercourses, corridors connecting areas of remnant vegetation, soil types supporting particular vegetation communities, the home ranges of many fauna species, as well as migratory species (Australian Government 2007). A person's capacity to understand biodiversity and various systems in nature is called a person's ecological literacy (ecoliteracy or environmental literacy) (Cutter-Mackenzie and Smith 2003; McBride et al. 2013; Palmberg et al. 2016). In addition to knowledge, an ecologically literate person has awareness, positive attitudes and values, and practical competence to preserve the environment (Orr 1992). He/she is able to take a holistic view when preserving and managing biodiversity to maintain ecological services.

Local and global understanding of inter-ecosystem interactions and dependencies is still evolving. Diverse systems are generally considered more constant (Tilman et al. 2006), reliable (Naeem and Li 1997), predictable (Berlow 1999), and less prone to change (Dovčiak and Halpern 2010) or invasion (Elton 1958) than simple systems. It empowers a natural system to absorb and recover from detrimental human impacts, and enhances sustainability (Australian Government 2007). Understanding of the major threats to biodiversity and the importance of preventing, halting, and reversing processes of degradation is increasing. However, there is a decreasing trend in biodiversity due to human actions (Primack 2010; Fryxell et al. 2014). Biodiversity is threatened by various human activities or their effects: human-induced changes in land cover that decrease and fragment the habitats of various species, invasive alien species, pollution, overuse of natural resources and climate change, as well as a range of socio-scientific factors (Hamble and Canney 2013). All these issues have led to an increasing awareness of the importance of preserving biodiversity not only for the well-being

of humans but also for moral reasons to preserve it for its own sake (Diaz et al. 2006). Public concern over biodiversity loss and ecosystem damage is reflected in a growing number of initiatives. These range from civil society and local community action to international, national, and local laws, policies, and regulations aimed at protecting, conserving, or restoring ecosystems.

Conversely, the failure to adequately avoid or minimize the impacts of operations on biodiversity poses growing threats and risks that can materially affect business's operations. Extinction is also of particular significance, since the loss of any species diminishes biodiversity. Extinction equates to lost opportunity, for example, to develop new medicines or other products. It also diminishes the collective well-being of society. Extinctions can also have significant effects on communities depending on cultural factors, particularly where there is a strong spiritual and/or emotional significance attached to the species. Community partnerships are therefore an effective means of achieving beneficial conservation outcomes.

Summary

Biodiversity refers to four dimensions: ecosystem, species, genetic, and cultural dimensions. The core idea of biodiversity concerns the inter-related nature of the living world changing constantly through evolution. Biodiversity is threatened by various human activities or their effects. However, the interdependence between biodiversity and humanity is critical for all peoples. Biodiversity is the basis of numerous ecosystem services that keep the natural environment alive, ranging from maintaining watersheds that provide fresh water to pollination and nutrient cycles, and the maintenance of clean air and atmospheric gases. Thus all communities ultimately depend on biodiversity services and resources. The preservation of biodiversity forms the core of sustainability and the protection of biodiversity is a prerequisite for sustainable development. A prerequisite for sustainable development and sustainability is the ability of a person to understand

biodiversity and its holistic character, and willingness to act together for beneficial preservation outcomes.

Definition (Biomimicry/Biomimesis)

The term biomimetic was first introduced by Otto H. Schmitt in 1969. The word meaning is bios (living, life, and living things in Ancient Greece), mimesis (imitation), or mimicry (imitate). In the literature, the words biomimetic, bionic, biomimicry are mostly used synonymously. Although the basic meanings of these terms are similar, their emergence and usage areas have changed over time (Dicks 2016). For example, while the bionic design is mostly related to the field of medicine, the term biomimicry or biomimetic based on the learning principle of nature is more evident in the design and architectural disciplines.

Biomimicry is a new discipline that explores the best ideas of nature and imitates these designs and is developed for people's problems (Biomimicry Institute 2016). Janine M. Benyus used this term for the first time in her book *Biomimicry: Innovation Inspired by Nature* in 1997 (Benyus 2002). Janine Benyus refers to the term biomimicry, which aims to be a bridge between biology and many other sciences in the use of the principles of nature: (Benyus 2002)

The biomimicry approach seeks the advice of nature at every stage of the design, from concept to creation and evaluation. Innovators discover and ask the correct functions of their designs that they want to finalize by working together with biologists at the design desk: Which organism or ecosystem enables them to survive by performing these functions?

Reed explains the biomimicry approach as follows (Reed 2004):

We are in the middle of a paradigm shift in looking and interacting with the natural world. This new line of thinking-biomimicry has a tremendous impact on the technological products and systems we have already designed. Biomimicry, an extremely important component of technology literature, is also an excellent example of the interdisciplinary nature of science and technology.

Nature has always produced many solutions to the problems it faced during its evolution. These solutions have been passed down from generation

to generation, such as the creature's ability to fly, swim, dig, run and, climb. The relationship of this capacity of nature with engineering inspires the formation of new tools, mechanisms, materials, and systems. Pump mechanism, controlled adhesion feature, honeybee structure ability, biological materials, and artificial intelligence are some of them. Biomimetic studies are also applied in different fields such as multifunctional materials, superior robots, and developed drugs.

The main idea behind all organic design concepts is learning from nature such as bionics, biomimetics, biomimics, biomechanics, biomechanics. The solutions developed by all living creatures to the problems faced by nature have directed humanity from past to present to approaches such as learning from nature and imitating nature. Therefore, these approaches have been accepted and developed in many fields such as medicine, architecture, engineering, design, and art (Altun 2019).

In biomimetic design, it is benefited not only from plants and animals but also from human biology. Deyoung and Hobbs compared the various examples given in this book to microorganisms, insects, flying animals, underwater life, humans, plants, nonliving objects, and inspiring examples and design practices (Deyoung and Hobbs 2009). Inspiration from nature involves many examples, including humans. There are many biomimetic examples designed from human DNA to a computer memory system, from human muscles to robotics, from the cochlea to headset, inspired by human biology (Kokturk and Altun 2018; Lurie-Luke 2014; Macnab 2012; Treehugger 2016).

Ten Inclusive Principles of Nature

In order to better understand the concept of bioinspiration, the inclusive principles of nature must first be known and understood. Basically, nature has ten inclusive principles (Serna and Barragan 2017). Therefore, these inclusive principles are the source of inspiration from nature.

These ten principles can be summarized as follows (Nature's Unifying Patterns 2016):

- Nature uses only as much energy as it needs.
- Nature recycles all materials. One's waste is another's treasure.
- Nature supports diversity. It is able to stand and resist the chaos and noise it brings.
- Nature does not maximize, optimizes. It establishes a balance between entering and leaving. It never overdoes it.
- Nature rewards collaboration and common work.
- Nature works on knowledge, proceeds with knowledge. There are feedback mechanisms.
- Nature uses only chemicals and materials that are safe for living things.
- Nature uses already existing and abundant resources, keeping rare resources in its constitution only sparingly.
- Nature keeps up with the settlement and responds. However, only by using the information in the environment and giving the appropriate answer can survive (adaptation ability).
- Nature correlates function and form. So it does whatever it has to do with minimum energy and materials.

Inspiration Forms in Biomimetic Design

With the use of biomimetic in technology and design, inspiration patterns were discussed by different researchers, and different figures of these forms were presented in the researches. But first, the concept of the inspiration forms in biomimetic has been proposed by Biodesign Team Turkey. This classification made by the Biodesign Team Turkey is as follows (Biodesign Team Turkey 2016):

Formal Inspiration: It can be defined as an imitation of the formal features of the organism. Formations observed in nature are different from man-made structures in terms of "scale," "function," and "formation processes." Despite this difference, the material has been

used as an inspiration by many architects and engineers with its energy conservation, lightness, as well as its durability. From ancient times to today, human beings have benefited from nature inspiration in every field. Biomimetic inspiration has been in life for thousands of years, such as hieroglyphic fonts in ancient Egypt consisted of motifs, for instance, birds and leaves in nature, and ancient motifs are dominant in the works of art of ancient civilizations. Many architectural structures and products, including forms inspired by nature, can also be cited in the design area. Types of inspiration from nature can be classified as herbal, animalistic (zoomorphic), humanoid (anthropomorphic), microscopic, and shaping of living environments of organisms (Yeler 2012).

Physiological Inspiration: It is defined as an imitation of formal or structural features of the organism for utilitarian purposes. It is within the definition of physiological inspiration to examine a specific feature, behavior, or functioning of a biologically defined organism or ecosystem and to use the data obtained to solve the design problem. An example of physiological inspiration is the self-cleaning glass developed by Bharat Bhushan using the lotus leaf's ability to self-clean. This design was developed based on the principle of keeping the water on the surface of the lotus leaf to remove dirt from the leaf (Dunster 1997). Similarly, a small wheeled vehicle produced to obtain maximum volume using the minimum material designed by Daimler Chrysler can be given as examples. The shape of this vehicle is designed by inspiring from boxfish (*Ostracion meleagris*). In the design of the vehicle, the relationship between the movement characteristics and shape of the fish was used. These and many other examples can be multiplied for physiological inspiration (Vincent et al. 2006; French and Ahmed 2010; Yoon et al. 2014).

Behavioral Inspiration: It is defined as being inspired by the natural processes (reproduction, birth, growth, decay, etc.) of the organism or living communities, or the behavior of living things, their interactions with the environment.

Different examples can be presented for this form of inspiration, which gained more importance in the architectural field with the developments in technology (Gruber 2011; Pawlyn 2011; Kokturk et al. 2019). The first example is the study analyzing how much the Tokyo subway line, which is also made using the shortest path finding feature of Slime molds, also called smart molds, overlaps with the real subway line (Tero et al. 2010). Slime mold is a eukaryotic living thing that feeds on oats. In this study, a small-scale of Tokyo metro network map has been dissolved into slime molds and this solution has been shown to overlap substantially with the established network. Other than this, there are also studies with slime molds, and motorways of countries such as America, Spain, England are resolved (Adamatzky and Jones 2010). As can be seen from these studies, slime mold is directly included in the process. Moreover, another study in which living things are incorporated is the process of developing a building block using mushrooms. The first studies of this block, mushroom included, have been produced by Ecovative and there are currently building blocks and additional design objects produced by this company (Younsung and Daniel 2019; kim and Ruedy 2019). Furthermore, researcher Andrew Adamatzky predicts that these designs may be used as microprocessors, which are the computer brain of the future, in the study of the logic gate models of Slime mold and other mushrooms (Adamatzky 2010).

Examples Mimicking to Nature in Terms of Material in Biomimicry

One of the areas using most in the concept of biomimicry is architecture and design. Leonardo De Vinci can be cited as the father of biomimetic design. Leonardo da Vinci used nature observations in many of his works. For example, he designed flying instruments by observing the flights of birds. Researcher Wilhelm Barthlott discovered in his research on the lotus leaf that the

leaf has sticky crystals that have small bubbles and repel water. Dirty molecules on the surface of the lotus leaf rise by means of the bumps on the leaf and can be easily collected with water droplets. This feature of the lotus leaf, which leaves pollutants behind, has been applied by Barthlott to various products such as exterior painting. This feature is known as the lotus effect and used in materials such as textiles, wood, glass. There are numerous small bumps and a wax-like layer on the lotus leaf at a height of 0.005–0.01 mm. In this way, water drops can remain on the upper points of the leaf. Due to this limited adherence, the droplets roll over the leaf quickly, and while rolling, they remove the soil pieces from the leaf (Deyoung and Hobbs 2009). It is used in areas such as the cleaning of high skyscraper glasses, the cleaning of automobile surfaces, and outdoor wall stain by imitating the formal characteristic, and adhesive crystal structure of the bubbles of the lotus leaf.

Penguins have a clear vision, despite the intense brightness of sunlight at the poles. These animals have a liquid in their eyes that allows them to filter the blue and ultraviolet colors of the solar spectrum. The fact that the researchers transferred the superiority of the penguins to the design with an orange filter caused the welding masters to use a more transparent and safe orange mask and screen than the masks previously used. Furthermore, orange-colored sunglasses provide pilot, sailors, and skiers a clearer view in bright

light, haze, and fog. Orange glasses are also thought to help patients with eye disorders caused by cataracts and macular degeneration (an eye disease that does not affect your central vision while blurring your central vision) (Deyoung and Hobbs 2009).

British doctor Ken Philips, who worked 15 years ago to prevent injuries in motorcycle accidents, found that even the safest helmet could not stop the rotation of the head immediately after the collision. Philips later realized that nature had a great invention to protect man's head. The human skin, in this example, the scalp provides a movement against moving in the direction of the effect, thereby reducing the effect of pressure on the skull. Dr. Philips suggested that covering the helmet with a thin material such as the scalp will prevent injuries and protect users' skull and brain and created Superskin technology. The new helmet design has decreased injuries by 67.5% according to the test results. The material coated on the helmet has a flexible structure like human skin and was developed by taking inspiration from this characteristic.

The moth is a living being that flies in the dark and has large eyes. It has a wavy protruding structure that allows these large eyes to see better without reflecting the light and to do this without appearing to other living things (Fig. 1). The transfer of this structure to the design has resulted in an innovative material. Inspired by this complex microstructure in the eye of the moth, a

Biomimicry, Fig. 1 (a) Moth eye under electron microscope, (b) moth eye structure inspired glare-resistance screen coating

Biomimicry, Fig. 2 Morphotex fiber inspired by Morpho butterfly (antenna.sciencemuseum.org.uk)

plastic film has been developed. This film is applied to mobile phone screens, allowing the phone screen to not reflect and use less light to illuminate the screen, thereby extending battery life. This material can be used in many areas such as solar panel, glasses, as well as on phone screens.

A Japanese textile company that mimics the wings of the Morpho butterfly has created Morphotex fiber using very thin wavy polyester layer and nylon (Fig. 2). This structure, which is 70–100 nanometer thick each layer, controls the scattered light tabs and creates red, green, blue, purple colors. This technology, which provides color formation without using stain, is also important in terms of sustainability in energy.

The Gecko gripper is another good example of a material-based biomimetic. Gecko lizard is a type of lizard that can cling to a surface with dry

adhesion. Under the animal's feet are microstructures (seta) and thousands of branched nanostructures (spatulas) (Bhushan 2009). These spatulas provide the grip between Gecko's feet and the surface it climbs thanks to the Van der Waals ties. Although the force of a single spatula is very weak, the force resulting from thousands of spatulas is large enough to carry the weight of Gecko, giving it speed and maneuverability. In this way, Gecko can move on any horizontal and vertical surface without the need for any chemical secretion. Inspired by the structure of the Gecko foot, the researchers copied this structure. Mark Katkosky and his team, who studied robots at Stanford University, designed a robot named Stickybot, which can climb the wall and looks like Gecko. The same team also developed a wearable garment that would allow a person weighing about 70 kg to climb a building with a glass outer surface. Another group of researchers

from the University of Massachusetts developed an adhesive tape, almost the size of a shopping voucher, capable of carrying the 320 kg load they named GeckSkin, using the sticking feature of Gecko. This tape can not only carry large loads with its small parts but can also be removed without leaving any traces from where it adheres.

Living in the Namibian Desert, one of the driest regions in the world, the black colored fog beetle lifts the back of its body upwards to obtain water from dew and fog. Microgrooves and protrusions on the insect's hardened chitin layer help to direct the insect from the back to the mouth by condensing the fog with dew. Also, the combination of hydrophilic and hydrophobic areas in this microstructure increases the amount of water directed (Naidu and Hattingh 2003). With this feature, the fog beetle can collect enough water to meet 40% of its body weight every day. This feature of this insect ensures its survival in difficult desert conditions. Designer Pik Kitae has developed a bottle called “Dew Bank” by taking advantage of the fog bug's water retention feature to provide water to millions of people who do not have access to water. The protruding stainless steel dome of this bottle becomes cooler than air in the morning, transferring the grains of dew sliding over it to the channel surrounding its base and allowing it to accumulate there. It is suggested that at least one glass of water will be collected with the dew bank bottle.

Examples Mimicking to Nature in Terms of Design in Biomimicry

The Crystal Palace built in London and the Eiffel Tower in Paris are examples of biomimetic design in architecture. The Crystal Palace was built in London for the first World Fair in 1851. This structure, which combines glass and iron, is considered a marvel of technology. A landscape architect named Joseph Paxton designed this building by observing the structure of the leaves of the lotus (*Victoria Amazonica*) plant growing Victoria in Amazonia. Paxton likened the glass parts of the structure to the leaf itself and the iron carriers to the complex and cross veins of the leaf (Fig. 3). As a result of this simulation, it designed a light and solid roof that covers a wide area by using glass and iron. Similarly, the Eiffel tower, one of the first examples of biomimetic design in architecture, was inspired by the structure at the head of the thigh bone. Hermann Von Mayer professor of anatomy in Zurich observed that the structure at the head of the thigh bone consists of many intertwined curved structures. Swedish engineer Karl Culmann realized that this structure is important in engineering and is resistant to the effect of the pressure on it, and revealed that the structure of the thigh bone transfers strength from the hip to the long leg bones in the best way. French structural engineer Gustaff Eiffel applied these principles to the building and built the Eiffel Tower in Paris in 1889 (Rao 2003).

Biomimicry, Fig. 3 (a) The Crystal Palace, London, (b) Amazon lotus flower (Meadows 1999)

The application of the structure of the thigh bone to the building gave the building durability and eliminated the ventilation problem. Application of the grid structure of bones in architecture and design reduces the material requirement and increases the strength of the building.

Another example of biomimetic approaches in architecture is the Munich Olympic Stadium, under which Frei Otto was engineered and completed in 1972. The system used here is inspired by the shape of the Alpine mountains. Spanish architect and engineer Santiago Calatrava, on the other hand, takes the functional aspects of forms in nature as a starting point in their designs. Milwaukee Art Museum (Quadracci Pavilion), completed in 2001, Calatrava provided a new function to the building mimicking the form in the structure. The building is in the form of a bird wing and has a collapsible roof system. While the wings open up during the day, they control the sunlight entering the museum, and they close at night and in bad weather conditions, protecting the museum against external influences.

Termite (*Macrotermes Michaelsoni*) especially living in the tropics is a kind of insect, also called white ant. These insects, which look like ants, form huge structures in the form of towers on the ground. At the same time, termites engaged in farming for food chains provide the air conditioning and ventilation systems of the nest with this tower-shaped structure (Fig. 4). They optimize the temperature in the housing with heat from the sun. The temperature inside is the same as the outside temperature. This ventilation method was applied

by Architect Mick Pearce in 1996 in the Eastgate building. The building as a residential is the first naturally cooled building. With this building designed the mimicking termites, a high level of energy was saved.

Summary

Biomimetic which combines technology and biology is an exciting branch that is frequently used today. There is a new understanding that biomimetic carries to the world of science: "Not learning things about nature, necessary learn from nature for innovation." This new apprehension has changed the view of nature and design. Nature contains many technologies. Therefore, it is clear that natural systems can be applied to many sectors.

The main idea at the basis of all concepts such as bionic, biomimetic, biomimicry, biodesign, biomechanics, organic design is learning from nature, inspiration from nature. The solutions developed by the living beings in nature against the problems faced have directed the designers and engineers to approach such as learning from nature and mimicking nature. These approaches have been accepted in many fields such as medicine, architecture, engineering, design, and art and they maintain their development.

In the relationship between design and nature, now it was passed through beyond simply copying the format into the product. In the problems encountered by examining the systems, methods, and functions of nature, the resources that can

Biomimicry, Fig. 4 (a) Termit yuvası, (b) Eastgate binası

perform similar functions in nature are searched and the application is started by seeking the solution in nature.

Examples of biomimetic design arise from observations in nature, as well as studies in which different disciplines that require biological examinations work together. Examples of biomimetic design consist of designs inspired by nature's structure, function, and forms. When the examples are examined, the designs that mimicking nature are divided into two classes, in terms of material and structure. Mimicking in terms of structure is classified as structural and textural, and the constructional structures are categorized as a structure where the function constitutes the architecture and the structure in which form generates the architecture. In the material, by being inspired by nature in terms of form and functionality, the product can be obtained by directly adding the living being into it. As a result, with the developing technology, the design has started to take a very different form by being inspired by nature in different ways. It is predicted that many technological product designs will be realized in the future not only through inspiration but also with the cooperation of nature.

Definition

In the same way that industrialization brought the economic development of nations, it also introduced increasing pollution indices that, in addition to environmental degradation, caused serious problems in the self-sustaining growth of the food chain, or led to the deterioration of human and animal health. Even many antibiotics became ineffective due to the action of these pernicious elements which, basically, can be classified into two groups, heavy metals and polycyclic aromatic hydrocarbons (PAHs). Certainly, the resolution of this issue is quite complex given that, in addition to the abovementioned damages, they also constitute a strong barrier to the economic growth of nations, especially those that lack the resources to fight the environmental pollution of soils. Against this scenario, bioremediation, a range of techniques, methods, and procedures that use as a foundation, tools provided by nature, is a uniquely successful remedy, whose effectiveness has been proven throughout the world. This entry describes the main stylized facts and defining characteristics of bioremediation.

Introduction

In accordance with the patterns marked by the Greco-Latin wisdom, the germ of Western knowledge, all the substances could be decomposed into four fundamental elements: earth, air, water, and fire (Ball 2004), which coexisted in several sciences such as medicine, pharmacopeia, or philosophy. Thousands of years later, in our most immediate present, with the sole exception of fire, the rest of the primary elements have been, in one way or another, contaminated by the effects of man's hand. During the last decades, the globalization of the economies as well as the late industrialization of some nations has resulted in economic growth that originally was inextricably linked to pollution and environmental deterioration (Briffa et al. 2020; Su et al. 2014), being particularly pernicious for the environmental habitat or the human health the contamination

stemming from the so-called heavy metals (Jean-Philippe et al. 2012; Su et al. 2014) without forgetting the impact of the polycyclic aromatic hydrocarbons (hereinafter, PAHs) (Cristaldi et al. 2017). Regarding the consequences of heavy metals on the environment, the food chain, or on living organisms through bioaccumulation processes (Briffa et al. 2020), it can simply be determined that their effects are devastating. In fact, Hubeny et al. (2021) report that heavy metals can contribute to an increase in the resistance to the antibiotics administered to humans through their uncontrolled discharge in sewage, sewage sludges, and river waters.

Stricto sensu, heavy metal pollution is caused when human activities lead to excessive deposition of heavy metals in soils (Su et al. 2014), contaminating terrestrial watercourses (rivers, streams, lakes, etc.) and ultimately reaching the oceans. According to Mohan et al. (2021), among the long list of heavy metals that contribute most to the systematic poisoning of the biosphere, it should be pointed out: arsenic (As), cadmium (Cd), chromium (Cr), copper (Cu), lead (Pb), mercury (Hg), nickel (Ni), or zinc (Zn). The different

forms in which heavy metals can be present in soils are basically five (Lasat 1999): in the form of free metal ions, soluble metal complexes or oxides, hydroxides, and carbonates, as well as associated with the matter existing in soils or added to the structure of silicate minerals.

Note that when terrestrial soils undergo contamination from heavy metals, it is quite difficult to eradicate their effects (Su et al. 2014) and even more complicated to restore them to their original state. In this context, there exist very few alternatives available, being one of them bioremediation, a numerous group of relatively modern procedures, techniques, and methods that etymologically mean “biological relief.” Taking Cristaldi et al. (2017) and Kavamura and Esposito (2010) as a point of reference, the main branches of bioremediation can be summarized in Fig. 1.

Indeed, since it is to some extent a novel term, there is no widely accepted concept of it (Wang et al. 2021). Thus, while Merriam-Webster (MW 2022) defines bioremediation very succinctly as “the treatment of pollutants or waste (as in an oil spill, contaminated groundwater, or an industrial process) by the use of

Bioremediation,

Fig. 1 Main methods and procedures from which bioremediation is implemented

microorganisms (such as bacteria) that break down the undesirable substances,” Sharma (2020) provides a purely academic definition: “Bioremediation is a process where biological organisms are used to remove or neutralize an environmental pollutant by metabolic process. The ‘biological’ organisms include microscopic organisms, such as fungi, algae and bacteria, and the ‘remediation’ - treating the situation.” Whereas until not too recently, heavy metals pollution was not taken into consideration as much as air or water pollution, because it was difficult to control by the governmental authorities (Su et al. 2014) or because it is sometimes a priori more complex to detect than other sources of pollution, it has now become a global problem (Nriagu and Pacyna 1988) that concerns underdeveloped, developing, and developed nations authorities (Su et al. 2014).

In this framework, industrialized countries have chosen to substantially reduce the disposal of heavy metals by raising social awareness or

through ambitious bioremediation projects (Vischetti et al. 2022). This decrease can be illustrated in Fig. 2, which presents the evolution of emissions of five heavy metals in all the member countries of the European Union over the last 30 years.

According to this graph, created from annual data provided by the European Environment Agency (EEA 2022), it can be observed a drastic reduction of mercury and cadmium emissions, along with some worrying levels of chromium, lead, and nickel. However, many voices have accused the developed countries of being exposed to a double standard since large multinational corporations have outsourced the dumping of polluting substances in the soils of less economically favored countries (Khor 2010) through the controversial and immoral phenomenon of “exporting pollution” (Ben-David et al. 2021). In the face of this situation, bioremediation has emerged as a response to the global pollution excesses. In order to obtain a rough idea of the

Bioremediation, Fig. 2 Heavy metal emissions to the atmosphere from extractive activities in the European Union (1990–2020)

Bioremediation, Fig. 3 Global distribution of researches focused on the bioremediation (1987–2022)

implementation of bioremediation worldwide, Fig. 3 displays a choropleth map of the distribution by country of all English-language scientific papers that have addressed these procedures and their ancillary techniques and processes collected from the Scopus database during the period 1987–2022 (Scopus 2014). More specifically, the different countries in which studies of this type have been carried out are presented by the nationality of the corresponding author. Altogether, there are 8338 scientific papers produced in 121 different countries.

The leading countries in terms of scientific production and investigation in the field of bioremediation are India, the United States, China, and Canada, although it can be noticed that developing and underdeveloped countries (i.e., Niger, Panama, Papua New Guinea, Paraguay, Senegal, Yemen, or Zimbabwe) can also benefit from these activities.

The implementation of bioremediation is perhaps most needed in the less economically favored nations, since the effects of contamination, apart from having a highly negative impact on the natural habitats of these countries, have also served to undermine the foundations of their weak economies, contributing to the gradual impoverishment of the local populations. This pattern is particularly notable in countries located in the sub-Saharan African Region (Anyanwu et al. 2018).

Consequently, Fig. 4 lists all the scientific disciplines on which have been articulated the 8338 scientific papers mentioned before that studied bioremediation during the period 1987–2022.

Although clearly, these are a series of techniques and procedures whose genesis comes from the Natural Sciences (e.g., Environmental Sciences, Biochemistry, Biology, or Chemistry), it should also be emphasized their multidisciplinary character, given that not a few of the Human Sciences have approached their analysis, as is the case of knowledge domains such as Economics and Finance, Business and Management, Arts and Humanities, or Psychology, as can be appreciated in Fig. 4.

Rationale of Bioremediation Procedures and Techniques

The bioremediation concept was first coined in 1972 for the cleaning of the Sun Oil pipeline spill at Ambler, Pennsylvania, USA (Kumar 2020). Bioremediation is a method to remove pollutants from the environment, i.e., soil, sediment, and water, especially in wastewater and solid waste (Massoud et al. 2019; Motaghi and Ziarati 2016; P. Ziarati et al. 2019a, b). Generally, microbes are used to degrade organic pollutants. Mostly used microbes are bacteria, algae, and fungi. The most commonly used bacteria

Bioremediation, Fig. 4 Main areas of research related to bioremediation (1987–2022)

are *Alcaligenes odorans*, *Bacillus subtilis*, *Corynebacterium propinquum*, *Pseudomonas aeruginosa*, *Aspergillus niger*, *Candida glabrata*, *Candida krusei*, and *Saccharomyces cerevisiae* (Marzuki et al. 2020). The commonly used algae are species of *Chlorella*, *Chaetomorpha*, *Poly-siphonia*, *Ulva*, and *Cystoseira*. The fungi used are white-rot fungi such as *Phanerochaete chrysosporium*, *Pleurotus ostreatus*, *Cyanea versicolor*, and *Cyathus stercoreus* (Silva et al. 2019). The pollutants are oxidized or reduced by microbial enzymes. Generally, bioremediation is used to remove the organic pollutants that originated from anthropogenic activities such as household, agricultural, and industrial applications (Ojuederie and Babalola 2017).

The common pollutants removed by bioremediation techniques are household and petroleum products, heavy metals, oil and solvents, pesticides, agrochemicals, chlorinated compounds, xenobiotics, halogens, nuclear waste, normal hydrocarbons, dyes plastics residues, and sludge (Medina-Bellver et al. 2005; Ziarati et al. 2020).

Most of the bioremediation reactions involve oxidation and reduction phenomena (redox). In this process, a chemical species gives an electron (electron donor) to a dissimilar species that accepts the electron (electron acceptor). Consequently, the electron donor is oxidized, whereas the electron acceptor is reduced. The common electron acceptors in the bioremediation phenomenon are mainly nitrate, oxygen, manganese (III and IV), iron (III), carbon dioxide, and sulfate. Electron donors are fats, sugars, natural organic material, alcohols, fuel hydrocarbons, and a variation of reduced organic pollutants. Mostly bioremediation is carried out in aerobic conditions but, sometimes, anaerobic conditions are also used as per the requirements.

The plan, design, control, and optimized process is a complicated phenomenon that includes several factors such as microbe population, availability as well as the contents of contaminants, type of matrix, pH, temperature, and the availability of oxygen and nutrients (Fritsche and Hofrichter 2001; Rawe et al. 2006; Ziarati et al.

B

Bioremediation, Fig. 5 Advantages and disadvantages of bioremediation

2018). Normally, bioremediation is an inexpensive process and more sustainable in comparison to other methods. This method is applied either in situ or ex situ depending on the requirements. Such dichotomous characterization is established on the basis of several criteria, which include the cost, the nature of the site, and the type and concentration of contaminants (Sharma 2020). This approach has many advantages in comparison to other methods like a natural process, a wide range of applications, harmless by-products, in situ nature, inexpensive, coupling with other techniques, etc.

Figure 5 provides an indicative illustration of the different advantages and disadvantages of bioremediation.

Summary

Still, there are some challenges in bioremediation, and these include lack of knowledge about microbe proliferation in the field, glitches, and

handling of the microbe, and difficulty in confirming correct interaction or arrangement among microbes and the contaminant. Researchers are working for innovative ideas to include materials that are capable to inspire microbes. It is expected that in the future, technologies of bioremediation are likely will provide better situations for disabling limits due to microbiological factors. Besides, new methods are being planned to improve microbes' bioavailability to increase bioremediation efficiency. However, the microbes should be handling carefully to avoid any damage to human beings and useful animals, i.e., the treated soil, sediment, and water should be free of microbes. Briefly, bioremediation is an extensively recognized method for cleaning and has a bright future.

Other lines of research can be addressed to develop the potential of bioremediation, not only in terrestrial soils but also in oceans, especially in cases of petroleum contamination (Bacosa et al. 2022), highlighting the cases of the Exxon Valdez, BP Deepwater Horizon, or Prestige oil spills

(Atlas and Hazen 2011; Gallego et al. 2007). It would also be interesting to perform studies that carry out jointly specific case studies in the wake of seminal works such as Balba et al. (1991) or Devine (1992), in order to establish comparisons between the different sites and procedures in which bioremediation has been used, or to deepen the implementation of strategies such as bioaugmentation or biostimulation to ensure the continued viability of these processes (Tyagi et al. 2011). In any case, it should always be taken into account the two main differential facts of bioremediation according to Sharma (2020) and what they imply for the achievement of a clean environment, the accomplishment of a true green economy, or a mankind free of diseases of pollution origin: “Bioremediation is the most effective, economical, eco-friendly management tool to manage the polluted environment.”

BBBEE	Broad-Based Black Economic Empowerment
BEE	Black Economic Empowerment

Introduction

The South African legislature in 2003 enacted the Broad-Based Black Economic Empowerment Act (BBBEE). The word Black Economic Empowerment (BEE) is often used to refer to the legislation or policies related to the BBBEE. The Act is meant to promote the right to equality as stipulated in the Constitution by increasing the participation of black persons in the economy. The right to equal participation in the economy is essential in South Africa because of the colonial and apartheid-era that disfranchised black persons from benefiting and participating in the economy (Duffett et al. 2009; Ponte et al. 2007). The

World Bank report noted that South Africa is one of the most unequal countries in the world (World Bank 2018).

In 1994, the democratic government enacted legislation that was meant to facilitate radical economic transformation (Ponte et al. 2007). For these reasons, the democratic government enacted Restitution of Land Rights Act, National Empowerment Fund Act, Employment Equity Act, Competition Act, Skills Development Levies Act, Preferential Procurement Policy Framework etc. The Black Empowerment was formed in 1998, which released a report in 2001 (Emuze and Adlam 2013). The report noted that the aim of the Commission was the realization that the domination of business activities by white businesses and the exclusion of black people and women from the mainstream economy. The Commission defined black economic empowerment, and the definition was divided into a narrow and broad definition. The report argued that the narrow definition of black economic empowerment focuses on the entry and transaction activities of black people in business, particularly black economic empowerment (BEE) investment policies. The broader definition of BEE argued that the fundamental crisis in South Africa's economy was the exclusion of black persons from financial and economic resources. In that light, the report recommended, among other things, the stakeholders to steer investments towards areas of national priority, development of human resources, procurement policies, etc. Further it recommended the promulgation of BEE legislation (Black Economic Empowerment Commission 2001).

Broad-Based Black Economic Empowerment Act

The Act has a broad definition of a black person which includes Africans, Coloreds, and Indians. Further, it specifies that such persons must be South African citizens by birth, who became South Africa citizens by naturalization before 27 April 1994 or those who were entitled to citizenship before 27 April 1994. It also emphasizes

women, workers, youth, people in rural areas, and people with disability. Notably, the Act takes a broad approach to the concept of economic participation. Economic participation includes control of enterprises, facilitation of ownership, human resources and skills development, preferential procurement, and investment in enterprises that are owned and managed by black people (Broad-Based Black Economic Empowerment Act 2003).

Implementation

The Minister of the Department of Trade and Industry is responsible for the implementation of the Act and may issue codes of good practice on black economic empowerment. Brun (2014) explained the implementation of the codes of good practice. Codes of good practice may give a further interpretation of BBEE and categories of BEE entries, criteria for preferential treatment, and any other matter necessary to achieve the objectives of the Act. Organizations gain points based on their compliance. The points earned in each element of the scorecard are added together, and the total number translates into recognition levels and B-BEE status achieved. The BBBEE status is the determining factor in obtaining preference points when tendering for government work. Different sectors may have specific sector codes that are aligned to the default codes and published for comment, and the Ministry is responsible for the alignment of the codes. Stakeholders develop sector codes, for example, Financial Sector Charter, Chartered Accountancy Sector, and Construction Sector Code etc.. The verification agency comprised of approved auditors conducts procedures to assess, verify, and validate the scorecards. The purpose of verification is to reduce the risk of misstatements, provide assurance, integrity, and reliability of the statements (Brun 2014).

Companies listed on the regulated market, Johannesburg Stock Exchange are required to disclose the details of their BBBEE compliance and publish on an annual basis their scorecard. The scorecard ought to detail the level of compliance

with targets of black ownership, management control, and skills development on their websites (Naidoo 2016).

Literature shows a mixed reaction towards BBBEE. Pike et al. (2018) conducted qualitative research to comprehend the future of BBBEE on small, micro, and medium enterprises. The participants of the research revealed that the BBEE is resulting in economic strain, mixed economic outcomes, and economic progression. The research also showed that the ripple effect of the procurement policies is tender corruption, increased business costs, and incompetence. Further, a few participants expressed that the legislation should remain as is, while the rest were of the view that amendments were needed to equalize the economy and provide equal opportunities for all (Pike et al. 2018). Another qualitative research conducted on construction firms by Emuze and Adlam (2013) showed that the companies face commercial impediments in implementation of BEE.

Ponte et al. (2007) argued that employment outcomes had heavily limited the meaningful participation of blacks in the economy since 1994. Further, employment creation has been limited and failed to keep up with the growth of labor force resulting in rising unemployment. The legislation that was meant to assist young black professionals did not succeed (Ponte et al. 2007). The arguments are plausible because the World Bank (2018) released a report which showed that high unemployment remains the critical challenge for South Africa and the inability to generate sufficient jobs. The report also showed that the labor market is split into two, at one extreme is a small number of people with highly paid jobs in the formal sector and the larger population in the informal sector. Further, it highlighted that despite the challenges, there was progress in the reduction of poverty since 1994 (World Bank 2018).

Mbeki analyzed the plight of Africa and argued that:

BEE strikes as a fatal blow against the emergence of black entrepreneurship by creating a small class of unproductive but wealthy black capitalists made up of African National Congress politicians ... who have become strong allies of the economic

oligarchy that is ironically the caretaker of South Africa's industrialisation'. The objects of BEE were to co-opt leaders of the black resistance movements by offering them what looked like a massive transfer of assets at no cost. As a result, subsidiaries of BEE, namely affirmative action and affirmative procurement, created economic oligarchs to protect assets. (Mbeki 2009)

BEE is another transformation goal of the democratic government and indeed a necessary policy. The problem with policies is always implementation, which results in mixed reactions towards BEE. Nonetheless, the progress since 1994 cannot be ignored as there are more black people participating in the economy.

Summary

Black economic empowerment is a policy by the South African government to address participation in the economy of previously disadvantaged South Africans. The equal participation of previously disadvantaged persons is regulated by the Broad-Based Black Economic Empowerment Act and implemented by the Department of Trade and Industry. The participation in the economy includes, among others, control of enterprises, ownership, and skills development. Organizations gain points for compliance which is audited by verification agencies.

Sustainability

Definition/Description

The circular economy is defined as “a regenerative system in which resource input and waste, emission, and energy leakage are minimised by slowing, closing and narrowing material and energy loops. This can be achieved through long-lasting design, maintenance, repair, reuse,

remanufacturing, refurbishing, and recycling” (Geissdoerfer et al. 2017: 764).

Circular Economy

Introduction

In the last two decades, much attention was drawn to the concept of circular economy, both by researchers and practitioners (Ghisellini et al. 2016). Adopted widely in Europe and currently in Asia (Andersen 2007), the idea was appealing as it offered a new mindset for sustainability and sustainable business. Shifting away from the “linear economy” in which a business produces a product, the consumer buys it and it then goes to waste, the circular economy creates a cycle in which everything stays in the system, nothing goes to waste, and innovative design thinking is used to create even better products and systems.

Circular Economy Defined

Circular economy is defined as “a regenerative system in which resource input and waste, emission, and energy leakage are minimised by slowing, closing and narrowing material and energy loops. This can be achieved through long-lasting design, maintenance, repair, reuse, remanufacturing, refurbishing, and recycling” (Geissdoerfer et al. 2017, p. 764). Korhonen et al. (2018, p. 39) defined the circular economy as an economy “constructed from societal production-consumption systems that maximizes the service produced from the linear nature-society-nature material and energy throughput flow.” The authors also asserted that circular economy limits the throughput flow to a level that nature tolerates and utilizes ecosystem cycles in economic cycles by respecting their natural reproduction rates. It is defined by European Institutions as an economy “where the value of products, materials and resources is maintained in the economy for as long as possible, and the generation of waste minimized.” (Merli et al. 2018, p. 704). While there is no one agreed-upon definition, there are some common elements such as the value of natural and other resources, minimization of waste, and a close, circular loop.

While the idea of materials cycles has been around since the dawn of industrialization (Korhonen et al. 2018), circular economy as a concept is relatively new. The circular economy concept was introduced by Pearce and Turner (1990), based on industrial ecology, which emphasizes the benefits of recycling residual waste materials and by-products through, for example, the development of complex interlinkages. Since then, the concept of circular economy became the focus of academic research particularly in the last decade. A systematic literature review by Merli et al. (2018) revealed 565 articles on the topic, most of them published since 2010. The authors argued that circular economy is a topic in rapid development, and that it has been recognized both by public decision makers and academia as the way forward to balanced development.

Furthermore, many countries around the world (particularly in Europe, as well as in Asia and Canada) have been adopting a circular economy approach. China was the first country in the world to adopt a law for the circular economy in 2008 (Korhonen et al. 2018).

The Shift

The circular economy aims to transform the linear “extract-produce-use-dispose” economy, which was the main way of doing business for decades, generating high levels of energy, labor, and material waste. As such, circular economy is a closed-loop approach to the economy, focusing on the optimal use of resources, enhancing the use and preservation of natural capital and limiting risks by effectively managing finite resource stocks and renewable energy (Webster 2015). Stahel (2016) explained that while the linear economy is like a river, the circular one is like a lake.

Furthermore, the circular economy differentiates between technical and biological cycles: it promotes the production of goods in a way that technical and biological components can be separated and recirculated in the supply chain (Webster 2015). It would change economic logic because it replaces production with sufficiency: reuse what you can, recycle what cannot be

reused, repair what is broken, and remanufacture what cannot be repaired (Stahel 2016).

Benefits and Limitations

Successful circular economy contributes to all the three dimensions of sustainable development (Korhonen et al. 2018; Stahel 2016). The benefits for the environment are the most obvious ones, with extracting less natural resource a lesser harm is caused to the natural ecosystem and biodiversity. There are also societal benefits, such as employment, increased sense of community (Korhonen et al. 2018), and the creation of social capital through collaboration and trust. Finally, there are also economic and business benefits, such as reduced costs, increased value, and enhanced brand (Haski-Leventhal 2018). Circular economy can assist in achieving sustainable development and (at least some of) the United Nations Sustainable Development Goals (or the SDGs). These benefits will become more prevalent as climate change turns more prominent and dangerous, with governments putting additional pressure on business.

However, there are also some limitations and issues with the concept of circular economy and its implementation. Korhonen et al. (2018) detailed six such limitations: thermodynamic limits (e.g., cyclical systems consume resources and create wastes and emissions); system boundary limits (e.g., problems are shifted along the product life cycle); limits posed by physical scale of the economy; limits posed by path-dependency and lock-in (e.g., first technologies retain their market position despite of inefficiency); limits of governance and management; and limits of social and cultural definitions.

In Practice

Webster (2015) detailed three circular economy principles for action, which are useful to include here:

1. **Natural capital should be preserved** by exerting control and limiting the use of natural resources and by utilizing resources that are renewable in nature. The circular system selects resources and materials which are likely

to perform better and have multiple uses to allow for regeneration of those resources.

2. **Using resources optimally** so that products and their components can be of high utility both in the technical and the biological cycles of a product's life cycle. The zero-waste economy ensures that biological materials (e.g., paper and fabric) are composted and technical materials and man-made materials (e.g., plastic) are of high-quality design so that they can be retained and reused.
3. **Fostering system effectiveness** by designing products that can be remanufactured, refurbished, and recycled so that they can be utilized in a new supply chain and circulated continuously in the economy. The preservation of land, air, and water together with determination to reduce pollution and manage climate change are important components of the circular economy.

One approach to circular economy is based on the idea the customers are product users, not owners, and they need to return products back to the companies when they are done using them, or to another third party who can use them (Lacy and Rutqvist 2015). Instead of owning, users return, lease, rent, or share their products and return them back into the supply chain. This business model is designed to rid the world of one-time use products.

The Blue Economy

The blue economy has a similar approach to sustainability as the circular economy and shares some of its ideas and concepts. Gunter Pauli's (2010) book, "The Blue Economy: 10 years – 100 innovations – 100 million jobs," offered a move forward from the green economy. The idea of the blue economy (based on the notion that the sky, ocean, and earth from space all look blue) is that we can shift from scarcity to abundance with what is locally available. The main argument of this book is that some of the sustainable issues and solutions around sustainability and the green economy have trade-offs. For example, renewable energy is not yet affordable to all and there are

some issues with current technology that might affect people's health and the environment. Instead, the blue economy offers circular solutions with no negative trade-offs.

The blue economy is about connecting and combining seemingly disparate environmental problems with open-source scientific solutions based upon physical processes common in the natural world to create solutions that hold environmental and financial benefits. Pauli (2010) claimed that industrial processes and environmental issues can be addressed by using simpler and cleaner technologies. Instead of only focusing on cutting costs and reducing harm, the blue economy focuses on value creation and economic benefits via job creation, reduced energy use, and community building.

The blue economy website offers over 200 examples and cases to inspire business people and entrepreneurs to work according to their principles. One such case is of the innovative use of coffee waste to grow mushrooms. This reduces waste, creates food, and offers sustainability and financial gain at the same time.

It should be noted that the UN refers to the blue economy as ocean governance (Silver et al. 2015), but this is not the focus of this entry, which relates to circular economy.

Summary

In the last two decades, much attention was drawn to the concept of circular economy, both by researchers and practitioners. Circular economy is about creating a regenerative system in which resource input and waste, emission, and energy leakage are minimized by slowing, closing, and narrowing material and energy loops. The circular economy aims to transform the linear “extract-produce-use-dispose” economy, which was the main way of doing business for decades, generating high levels of energy, labor, and material waste. Successful circular economy contributes to all the three dimensions of sustainable development: environmental, social, and financial. However, it is also with some limitations and challenges.

Similar to the idea of circular economy, the concept of the blue economy was developed, to offer holistic solution without negative side effects for the environment. It is a more popular term than an academic one.

Definition

Although no specific definition is designated for this term, this concept has been previously defined based on the field of application and utilization. The blue economy refers to the sustainable utilization of ocean and coastal resources for economic growth, improved livelihoods, and job

creation while preserving the health of marine ecosystems. It is also regarded as an economic concept encompassing various economic activities in the ocean and coastal area, including traditional activities such as fishing, shipping, and shipbuilding, as well as newer activities such as offshore wind and wave energy, ocean-based aquaculture, and marine biotechnology. It is defined as the range of economic activities in the coastal zone and on the ocean, including shipping, fishing, oil and gas extraction, tourism, and renewable energy production. Generally, the blue economy mainly focuses on the responsible extraction and utilization of marine resources required to enhance ocean-based economies while adopting more balanced conservation measures to ensure resource sustainability.

Introduction

The “blue economy” or “sustainable ocean-based economy” comprises several economic and governmental sectors whose primary objectives are to responsibly boost economic and social development to guarantee the long-term sustainability of the seas and coastlines. These blue ecosystems and their resources, such as mangroves, are also known to protect beaches and coastal regions from unexpected storms and flooding, thereby facilitating habitat biodiversity, climate control, carbon storage, and detoxification. Marine and coastal ecosystems provide two-thirds of all critical services. Subsistence fishing and farming have benefited most indigenous people, especially in coastal settlements, from marine resources (Elegbede et al., 2023a, b; Okafor-Yarwood et al., 2020).

Over the years, incidents involving the extreme depletion of many aquatic resources due to anthropogenic activities, notably for profit generation, have been observed (Jolaosho & Olorunniyi, 2022). The effects of these stresses on the aquatic environment include acidification, pollution, ocean warming, eutrophication, fisheries collapse, loss of marine species, destruction of breeding grounds, and instability of ecosystems (Leadley, 2010; Naggar, 2020). This issue demands an immediate response since the adverse

effects will have long-term consequences for the planet's health. To protect these resources for a sustainable blue economy, it is necessary to employ proper management strategies. The blue economy is the sustainable use of ocean and coastal resources for economic development, better livelihoods, and job creation while maintaining the health of marine ecosystems (United Nations Development Programme, 2016). It includes historic operations such as fishing, shipping, ship-building, and recent activities such as offshore wind and wave energy, ocean-based aquaculture, and marine biotechnology. It is the spectrum of economic activity in the coastal zone and on the ocean, including shipping, fishing, oil and gas exploitation, tourism, and the generation of renewable energy (Halpern, 2015).

The world's foremost economists presented a technique for achieving sustainability many years ago. Nevertheless, Belgian economist Gunter Pauli created the notion of the blue economy in 2011, and the United Nations Development Programme embraced it in 2014. Since then, governments and stakeholders have recognized it as a crucial strategy for achieving sustainable development and tapping the potential of the ocean economy (United Nations Development Programme, 2016). In recent years, the blue economy idea has gained traction as the contribution of the ocean economy to sustainable development has been widely acknowledged (Brouwer & Heesterbeek, 2018).

Developed countries have embraced and implemented the recommended paradigm in various sustainable development applications (Martnez-Vázquez et al., 2021; Brears, 2021; Nash & Herscovitch, 2018; Elegbede et al., 2023a, b; United Nations Development Programme, 2016; Elegbede 2021; Krause, 2019).

Benefits of a Sustainable Blue Economy

A sustainable blue economy is necessary to attain the United Nations Sustainable Development Goals (SDGs) and maintain coastal and island populations' long-term prosperity and well-being. The ocean economy is anticipated to

quadruple by 2030, reaching approximately \$3 trillion (United Nations Development Programme, 2018). This economy has enormous potential for economic expansion, job creation, and poverty alleviation, especially in developing nations. In addition, the sustainable blue economy may play a significant role in tackling global concerns such as climate change, food insecurity, and biodiversity loss (United Nations Development Programme, 2018). It is seen as a technique for promoting sustainable development in coastal regions and tiny island governments and a possible means of combating poverty and inequality (Halpern, 2015).

The increasing popularity and acceptance of the blue economy idea were due to its capacity to govern and protect marine environments sustainably and healthily, cut emissions, and address climate change challenges. There has been a significant increase in the population of renewable energy sectors, with the ocean serving as the primary source of renewable resources. Wind, hydropower, and tidal energy are also associated with maritime ecosystems. For all energy sources in the water to be exploited, it is necessary to establish specific criteria. To create wind farms, for instance, industrial experts and workers must be consulted; this indicates that the ocean provides employment prospects in various industrial disciplines, particularly construction.

Further advantages of the blue economy include offshore wind, wave, and tidal energy generation; offshore fish farming; ocean sediments collected through dredging; and blue biotechnology, which uses marine resources such as shellfish, bacteria, and algae for medicinal and energy production reasons. The blue economy has often been employed throughout international business transactions as a mode of conveyance for commodities. The European Union (EU) and the United Nations (UN) have enacted measures and policies that will aid in preserving ocean resources and limiting the impact of climate change on the blue economy over a very long period so that these resources can be explored for their economic benefits in a more sustainable manner.

Differences Between the Blue Economy and Ocean Economy

The terms “blue economy” and “ocean economy” are frequently used interchangeably, although they have distinct implications. The ocean economy comprises all economic activities related to the ocean, including transportation, tourism, and offshore energy production. In contrast, the blue economy is a subset of the ocean economy that focuses on the sustainable use of ocean resources for economic growth and job creation while protecting the health of the ocean ecosystem (Ryabibin et al., 2019). The blue economy emphasizes the need for collaboration and stakeholder engagement in the sustainable management of ocean resources, which is another essential differentiator. When designing and implementing sustainable ocean policies, the blue economy considers the interests of all stakeholders, including local communities, government agencies, and the corporate sector (Voyer & van Leeuwen, 2019; Islam & Mostaque, 2016; Patil et al., 2018; Sarker et al., 2019; Bari, 2017).

The blue economy is more concerned with the health of the ocean ecosystem. It aims to promote the conservation and sustainable use of marine resources. At the same time, the ocean economy focuses primarily on the economic benefits derived from the ocean and coastal areas (United Nations Regional Information Centre for Western Europe, 2022).

Economic Activities in the Blue Economy

The contributions of industries involved in the blue economy concept while operating sustainably to ensure the sustainability of coastal and marine resources are as follows.

Fisheries and Aquaculture

The industry includes capturing wild fish and shellfish and cultivating aquatic plants and animals in marine and freshwater habitats. Almost

2 million Nigerians rely on the fishing industry, making it a significant business (Federal Ministry of Agriculture and Rural Development, 2019). The worldwide fishery and fishery product business is valued at over \$150 billion, and over 500 million people rely on the industry for their lives (Food and Agriculture Organization, 2020). The aquaculture industry has grown at a pace of 4.8% annually since 2000, making it the fastest-growing food production sector (World Bank, 2018). With an estimated value of \$1.5 billion, the fishing sector in Nigeria is a substantial economic contributor (Federal Ministry of Agriculture and Rural Development, 2019). In addition to overfishing; illicit, unreported, unregulated fishing; and the destruction of coastal and marine environments, the industry faces various issues (Food and Agriculture Organization, 2020). Poor infrastructure, low finances, and a lack of technological access are obstacles confronting the Nigerian fishing sector (Federal Ministry of Agriculture and Rural Development, 2019). Nonetheless, there is potential for sustainable growth, including expanding aquaculture, adopting sustainable fishing techniques, and using new technology (Federal Ministry of Agriculture and Rural Development, 2019).

Maritime Transport and Logistics

The marine transport industry comprises cargo shipping, cruise ships, and ferry services, among other operations (Krause, 2019). It is crucial in international trade and business, linking nations and regions by transporting products and people. Almost 90% of Nigeria’s import and export commerce is performed via its ports, making the marine industry substantially contribute to its economy (Nigerian Ports Authority, 2020). The worldwide marine transport business is worth more than \$375 billion. The shipping industry alone accounts for over 90% of the global commerce volume (United Nations Conference on Trade and Development, 2020).

Additionally, the industry employs millions of people, including sailors and port employees

(International Transport Workers' Federation, 2020). In Nigeria, the marine industry, directly and indirectly, employs approximately 100,000 people (Nigerian Ports Authority, 2020). Over-capacity, increasing competition, and a deficiency of efficiency are difficulties affecting the industry (United Nations Conference on Trade and Development, 2020). There are also worries over the sector's environmental effects, including greenhouse gas emissions and marine pollution. In Nigeria, the industry faces obstacles such as insufficient infrastructure, a weak regulatory framework, and insecurity in the Gulf of Guinea (Nigerian Ports Authority, 2020). There are prospects for sustainable development, including adopting new technology, such as digitalization, automation, and alternative fuels, and applying sustainable practices, such as enhanced energy efficiency and emission reduction (Nigerian Ports Authority, 2020).

Offshore Energy Production

Offshore energy production includes oil and gas extraction, wind and wave energy, and ocean thermal energy conversion. The oil and gas industry substantially contributes to Nigeria's economy, accounting for more than 90% of export profits and more than 70% of government income (National Petroleum Corporation, 2020). Approximately 30% of world oil output and 20% of global gas production originate from offshore sources, valuing the global offshore oil and gas business at more than \$200 billion (Hughes, 2020). The oil and gas industry in Nigeria contributes significantly to the country's economy, with an estimated value of over \$300 billion (Nigerian National Petroleum Corporation, 2020). The industry faces resource depletion, environmental consequences, and oil price volatility (Baker Hughes, 2020). In Nigeria, the industry faces obstacles such as insufficient infrastructure, a weak regulatory framework, and insecurity in the Niger Delta area (Nigerian National Petroleum Corporation, 2020).

Coastal and Marine Tourism

Coastal and marine tourism encompasses beach vacations, ecotourism, and cruise ship travel, among other things. Tourism is a rapidly expanding business in Nigeria, emphasizing the country's cultural diversity and natural features (Federal Ministry of Information and Culture, 2020). The coastal and marine tourism industry is worth approximately \$300 billion. More than 1 billion international tourists visit coastal regions annually (World Tourism Organization, 2020). The tourist business in Nigeria contributes significantly to the country's economy, with an estimated value of over \$1 billion (Federal Ministry of Information and Culture, 2020). Overtourism, environmental deterioration, and the effects of climate change are some of the issues confronting the industry (World Tourism Organization, 2020). Nigeria's industry needs more infrastructure, a weak regulatory environment, and no marketing activities (Federal Ministry of Information and Culture, 2020). Nevertheless, there are also chances for sustainable growth, such as creating sustainable tourist destinations, adopting sustainable practices, and using new technology (Federal Ministry of Information and Culture, 2020).

Biotechnology and Marine-Based Renewable Energy

Biotechnology and marine-based renewable energy involve the creation of novel marine goods and services and the use of ocean resources for energy production. Biotechnology is a rapidly expanding industry in Nigeria, emphasizing the creation of new marine-based goods and services (Federal Ministry of Science and Technology, 2020). The value of the worldwide biotechnology and marine-based renewable energy market exceeds \$200 billion, with tremendous development potential in sectors such as marine biotechnology, aquaculture, and ocean energy (International Energy Agency, 2020). In Nigeria, the industry is still in its infancy. Nevertheless, it could become a substantial economic contributor

(Federal Ministry of Science and Technology, 2020).

The industry faces obstacles such as a lack of investment, poor infrastructure, and research and development funding (Federal Ministry of Science and Technology, 2020). However, there is potential for sustainable growth, including creating new marine-based goods and services, implementing sustainable practices, and using new technology (Federal Ministry of Science and Technology, 2020).

Seabed Mining

Copper, gold, and zinc are among the minerals that mining may extract from the seafloor (International Seabed Authority, 2020). The value of the worldwide seabed mining industry exceeds \$50 billion, with tremendous growth potential as new technologies and rising mineral demand drive exploration and development. The industry faces obstacles such as increased awareness of the environmental effects of seabed mining, insufficient laws, and the need for further research and development (International Seabed Authority, 2020). Nevertheless, there are prospects for sustainable growth, such as developing sustainable mining methods and using new technology (International Seabed Authority, 2020).

Maritime Engineering and Construction

Marine construction and engineering aspects include developing and maintaining offshore structures, ports, and shipyards. Marine construction and engineering are a rapidly expanding industry in Nigeria that emphasizes building new ports and shipyards and maintaining and extending current infrastructure (Nigerian Ports Authority, 2020). The worldwide maritime construction and engineering industry is valued at over \$200 billion, with tremendous development potential in offshore wind, ports, and shipyards (Frost & Sullivan, 2020). The industry is a substantial economic contributor in Nigeria, estimated at \$2 billion (Nigerian Ports Authority,

2020). The industry faces obstacles such as a lack of investment, poor infrastructure, and research and development funding (Nigerian Ports Authority, 2020). However, there are prospects for sustainable growth, such as creating sustainable infrastructure, implementing sustainable practices, and using new technology (Nigerian Ports Authority, 2020).

Blue Carbon

Blue carbon is the carbon stored in coastal and marine ecosystems, including mangroves, seagrasses, and salt marshes. The worldwide blue carbon market is estimated at over \$50 billion. It has tremendous potential for carbon sequestration and emission reductions (United Nations Framework Convention on Climate Change, 2020).

The industry faces obstacles such as a better understanding of blue carbon's potential, weak laws, and further research and development. Nonetheless, there is potential for sustainable development, including protecting and restoring coastal and marine ecosystems and using blue carbon for carbon offsetting and sequestration (United Nations Framework Convention on Climate Change, 2020).

Challenges and Opportunities

Problems confronting the blue economy: overfishing, pollution, coastal development, and climate change are among the issues facing the blue economy. These obstacles may hinder the sustainable growth of the blue economy and coastal populations' means of subsistence. For instance, overfishing has caused the depletion of fish populations, which has economic and ecological repercussions (Costello et al., 2012). Likewise, pollution from plastic trash, pesticides, and oil spills has devastating consequences for marine species and environments (Gregory & Ryan, 2009). Coastal development and urbanization have also led to the loss and deterioration of mangroves, seagrasses, and salt

marshes, among other ecosystems (Pendleton et al., 2012). In contrast, climate change is generating sea level rise, ocean acidification, and changes in ocean currents and temperature regimes, all of which may impact marine ecosystems and the services they offer (IPCC, 2019).

Growth and innovation potential in the blue economy: Notwithstanding these obstacles, there are growth and innovation opportunities in the blue economy. For instance, sustainable aquaculture may offer a reliable food supply and revenue while safeguarding wild fish populations (FAO, 2020). In addition, the blue economy can provide employment, drive economic expansion, and contribute to the sustainable development of coastal towns.

Policies and measures to encourage the sustainable growth of the blue economy: Sustainable development policies and strategies must be implemented to overcome these obstacles and achieve the potential benefits of the blue economy. These policies and initiatives include establishing protected areas, protecting and restoring coastal and marine ecosystems, and reducing greenhouse gas emissions. To overcome these difficulties and support the sustainable growth of the blue economy, it is crucial to emphasize the integration of sectoral activity and the engagement of stakeholders. In Nigeria, for instance, the government has developed the Integrated Coastal Zone Management Project (ICZMP) to promote sustainable development in coastal regions by integrating sectoral operations and involving stakeholders (Shah & Ramesh, 2022). This initiative strives to solve coastal erosion, pollution, and overfishing challenges by applying laws, regulations, and management plans. In addition, Nigeria's Ministry of Environment has developed a National Biodiversity Strategy and Action Plan (NBSAP) to guide the protection and sustainable use of biodiversity in the nation (Kumar et al., 2021). This policy directs the country's protection and sustainable marine and coastal biodiversity use. It relates to the worldwide biodiversity objectives established by the Convention on Biological Diversity.

The blue economy may significantly alleviate poverty in coastal areas by providing employment, income, and food security. In Nigeria, for instance, the fishing sector employs and supports millions of people, mainly in coastal towns (FAO, 2020). Similarly, developing sustainable tourism may offer local populations jobs and income while safeguarding marine and coastal ecosystems (WTO, 2020). The potential of the blue economy in various regions vary by geography and the accessibility of marine resources and infrastructure. Through the growth of sectors such as fisheries, tourism, and renewable energy, the blue economy can provide substantial economic and social advantages in Nigeria, for example (Federal Ministry of Environment, 2020). In addition, the nation has enormous potential for the growth of the offshore oil and gas industry, which is a significant source of government income and job opportunities for its residents.

Future Directions

With an expanding worldwide population and need for food and energy, there is a growing need for the sustainable use of marine resources, which bodes well for the future of the blue economy. The blue economy is anticipated to expand and be a significant economic growth and social development source. To guarantee the conservation of marine and coastal ecosystems and the well-being of coastal populations, however, this expansion must be guided by sustainable development principles. The sustainable growth of the blue economy requires a comprehensive strategy that considers its economic, social, and environmental elements. Moreover, the sustainable growth of the blue economy demands global cooperation and collaboration since the blue economy is a global problem that impacts all nations and areas. Participation from all stakeholders, including governments, the commercial sector, civil society, and local communities, should be needed.

It is essential to implement laws and regulations that encourage the conservation of marine resources to maintain the long-term growth of the

blue economy. Implementing measures such as marine protected zones, sustainable fishing techniques, and catch limits may be necessary. Encouragement of sustainable economic activities, such as sustainable aquaculture, ecotourism, and marine-based renewable energy, is also advantageous and may be accomplished via R&D funding and private sector involvement incentives. In addition, it is necessary to adapt to the consequences of climate change on the blue economy by developing steps to address increasing sea levels, ocean acidification, and severe weather events. Adopting an integrated approach to coastal zone management that considers the blue economy's economic, social, and environmental components and incorporates all stakeholders may contribute to sustainable development. Global pollution, overfishing, and climate change need international collaboration. Inclusivity and poverty reduction may be promoted by integrating underrepresented populations and establishing income-generating opportunities.

Summary

The blue economy is the sustainable use of ocean and coastal resources for economic development, enhanced livelihoods and employment, and the health of ocean ecosystems. It includes fisheries and aquaculture, maritime transportation and logistics, offshore energy production, coastal and marine tourism, biotechnology and marine-based renewable energy, seabed mining, marine construction and engineering, and blue carbon. The blue economy can stimulate economic development and enhance coastal towns' living standards. Nevertheless, the sustainable growth of the blue economy faces various obstacles, such as overfishing, pollution, coastal development, and climate change, which may have a detrimental impact on the lives of coastal populations and the sustainable development of the blue economy. Sustainable development policies and strategies must be implemented to overcome these obstacles and achieve the potential benefits of the blue economy. This initiative encompasses sustainable management of marine resources, promoting

sustainable economic activities, adaptation to climate change, integrated coastal zone management, international collaboration, inclusion, poverty reduction, research and monitoring, and education and awareness.

Description

In the last decades, business strategy was dominated by the competition and rivalry strategies. For instance, Porter's five forces has been one of the most influential models not only in academia but also among business practitioners as well. Porter utilized five explanatory variables to explain superior or inferior performance of the companies (Grundy 2006). These five explanatory variables were: (1) the bargaining power of the buyers, (2) entry barriers, (3) rivalry, (4) substitutes, and (5) the bargaining power of the

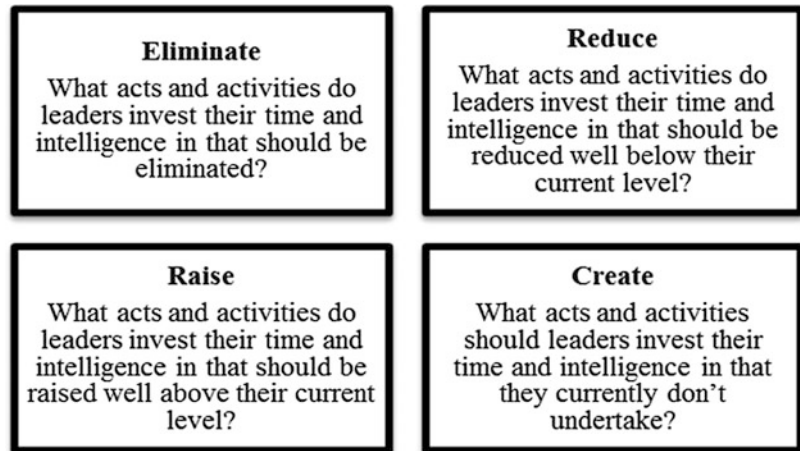

suppliers (Porter 1980). Prior to Porter's contribution to business strategy literature, Industrial Organization (IO) economists attempted to analyze relation between industry structure and performance through empirical work and eventually Porter's framework for industry analysis helped broaden the supply-demand analysis of individual markets (Karagiannopoulos et al. 2005). Traditionally, these frameworks were imperative to provide guidance on the business strategy where there is an existing market and competitive landscape. It is observed that in existing markets, competition grows over time which in turn puts pressure to the price points and turns the products into commodities. In the existing markets, the customer demand and the supply are already known by the industry players. There is sufficient visibility into the competitor share data and companies thrive to increase share from the competitors. Price wars, cost-cutting, and several different examples of share gain strategies are applied to be able to win in the marketplace. These examples represent the "Red Ocean" where there is already known market and customer demand.

As opposed to "Red Ocean," "Blue Ocean" represents the unexplored market where there is no or limited competition. Blue Ocean markets are yet to be explored and hence bring a myriad number of potentials such as new product introductions, new business models, higher margin, and profitability opportunities.

Tactics to Develop New Blue Ocean Strategies

Adoption of "Blue Ocean" strategy translates into driving costs down while at the same time driving value up for the customers (Kim 2005). According to Kim and Mauborgne (2014), there are five main points of distinction that companies should start considering when thinking about "Blue Ocean" strategy: (1) Competition should not be at the center of strategic thinking, (2) industry strategy can be shaped by the companies, (3) strategic creativity can be unlocked systematically, (4) execution can be integrated into strategy development, and (5) with a structured model,

Blue Ocean Strategy,
Fig. 1 Blue Ocean
Leadership Grid (Kim and
Mauborgne 2014)

B

companies can avoid market-competing traps and achieve market-creating innovations. These distinction points help companies challenge the traditional beliefs in the world of strategy and enable them to rethink about innovation in their respective businesses. According to Leavy (2005), “Blue Ocean” strategy planning through utilization of strategy canvas is applicable to any type of industry including business to business setting. With the help of strategy canvas, companies can find Blue Ocean for their businesses (Alam and Islam 2017).

Kim and Mauborgne provided a framework for “Blue Ocean Leadership Grid,” which is an analytic tool that challenges people to think about which acts and activities leaders should do less of because they hold people back and which leaders should do more of because they inspire people to give their all (Kim and Mauborgne 2014). According to authors, effective leaders create value utilizing the four categories laid out in the grid: (1) eliminate, (2) reduce, (3) raise, and (4) create (Fig. 1). This Blue Ocean leadership can help transform the organizations through improving leaders and employee’s performance (Alam and Islam 2017).

higher margin, and profitability opportunities. As a matter of fact, according to a study conducted by Kim, 2005, only 14% of all studied business launches were made within the Blue Ocean markets, but these 14% achieved 38% revenue impact and about 61% of profit impact, compared to the majority of 86% business launches in red oceans, which were able to get 39% of the total profit impact (Kim and Mauborgne 2004). This result reinforces the power of “Blue Ocean” strategy and its potential impact on driving business outcomes. According to Basri, Ghadzali, and Ismail (2011), “Blue Ocean” strategy generated positive outcomes in organizations such as IKEA, Starbucks, Philips, and non-profit organizations. These case studies show the impact of this strategy and can set a benchmark for other organizations and industries as “Blue Ocean” strategy has the power of making competition irrelevant and generates a new marketplace for brand-new demand.

In today’s world where there is increased competition, increased supply surpassing demand, and ever harder supply chain and competitive landscape post-Covid, companies should take a hard look into “Blue Ocean” strategy to create sustainable performance in their businesses.

Summary

As mentioned before, “Blue Ocean” strategy brings a myriad number of potentials such as new product introductions, new business models,

Board Capital

Fabrizia Sarto

Department of Economics, Management, Institutions, University of Naples “Federico II”, Naples, Italy

Board intellectual capital; Board knowledge, skills and relationships; Human and social board capital

Definition

The “Board Capital” is the combination of human and social/relational capital of board members (Hillman and Dalziel 2003). More specifically, scholars define the Board Capital as the sum of knowledge and skills that directors hold thanks to their educational path and work experiences and the set of relationships established by directors with internal and external stakeholders.

Introduction

Characteristics of board members that influence firm performance have increasingly been of interest of scholars and practitioners (Daily et al. 2003; Gupte and Paranjape 2014; Agrawal and Chadha 2005). In this regard, a relevant issue in the academic and practical debates has been to answer the question of what enhances directors' effectiveness in value maximization. Despite there has always been a tacit consensus that individual director characteristics and qualifications are relevant aspects (Jensen 1993), most of studies have mainly focused on broad board attributes such as

board size, composition (e.g., independence), appointment methods, structure, equity ownership, and diversity (i.e., gender and ethnicity) (Johnson et al. 2012).

However, against the main stream examining the surface properties of the board of directors, a number of articles have recently explored the determinants of board functioning by focusing on its relational and human capital (Berezinets et al. 2016). Board capital is the sum of human and social/relational capital of board members (Hillman and Dalziel 2003). More specifically, scholars define the board human capital as the expertise, experience, knowledge, and skills that board members possess thanks to their education and work experiences, ranging from the high educational level to the expertise in a specific sector. Differently, scholars identify the board relational (or social) capital in the relationships established by board members with internal and external stakeholders.

Hillman and Dalziel (2003) have been the pioneers of the board capital construct. The authors have claimed that directors contribute to the board through their expertise, experience, and skills, as well as social links and networks. In this regards, scholars have argued that the effectiveness of board functioning relies on the intellectual capital of board members, that is able to overcome the inconclusiveness of the empirical evidence examining the relationship between the surface properties of the board of directors and firm performance until then. Indeed, according to the authors (Hillman and Dalziel 2003), this construct would have allowed to overcome the weakness of choosing one theoretical approach over another on the board (Nicholson and Kiel 2004) and the inability of typical board composition/structure measures to predict its effectiveness (Dalton et al. 1998; Hillman et al. 2000). Differently, board capital represents the preconditions of the board's ability to engage in all governance activities, such as monitoring or resource provision roles, by explaining and arguing all the theories concerning the board governing role (e.g., agency theory, resource dependence theory) (Kor and Sundaramurthy 2008; Nicholson and Kiel 2004).

To appreciate how the board capital concept has been able to overcome the limits of the

traditional board demographic approach, it seems crucial to understand the process that led scholars to develop it. In particular, it is worth noting that the formulation of the above-mentioned concept takes place thanks to two main contributions (Zona 2013; Berezinets et al. 2016). Within a first paper of 2000, Hillman, Cannella, and Paetzold argue that the traditional board members classification according their independence status allows to proxy for the antecedents of board monitoring function but not for the service role. In their paper, the authors claim that it is possible to overcome this limit by using alternative classifications, for example by measuring if board members have work experiences in comparable firm, or an educational degree in a specific area (e.g., law, banking, commercial). Therefore, the authors develop the belief that building on the "resource dependency theory" perspective, the effectiveness of board directors in providing resources to the company relies on their social and human capital.

As a further step in the development of the Board capital construct, 3 years later, Hillman and Dalziel (2003) publish a seminal paper on the *Academy of Management Journal* and refer for the first time to the human capital theory and to the social capital theory. More specifically, they argue that board members' capital is able to allow the governing body to perform not only the service role, but also the monitoring one. Indeed, the researchers assert that the directors' independence does not proxy for the members' ability to monitor but for their incentive to do so. This incentive can moderate the board's ability which in turn only depends on the members' relational and human capital.

In this perspective, the literature highlights that the human and social capital is the best proxy to appreciate the board's ability to perform its functions. It is worth noting that the concept of the human and social/relational capital, and the related measures represent the only ones that allow to explain and argue all theories related to the governing roles of the board (Nicholson and Kiel 2004). The intellectual capital held by the governing body thus represents the precondition of the board's ability to carry out all its activities.

Scholars argue that the board's ability to carry out all roles relies on the resources that directors provide to the board (Berezinets et al. 2016; Sarto 2016).

The advantage of employing this approach is twofold. Indeed, on the one hand, as previously stated, it allows to grasp the ability of the governing body to fulfill all its roles and activities, from the monitoring role to the provision one, overcoming therefore the competition between the different theoretical approaches. On the other hand, it also allows to look at the board as a collegial body, representing a proxy to appreciate some of the processes defined by Forbes and Milliken (1999), such as the presence of cognitive conflicts or the use of the knowledge and skills available in the board (Sarto 2019).

Aside the theoretical contributions that have developed the Board capital construct, it is also relevant to mention those studies that have identified the dimensions that characterize the board capital. In this regards, Haynes and Hillman (2010) conceptually identify the "breadth" and "depth" as two dimensions of board capital. While the former captures the human and relational capital heterogeneity of board members, the latter refers to the embeddedness of the board in the focal firm's industry. Some authors have enlarged the dimensions of board capital by identifying also its quality, in terms of educational level, as well as professional prestige. Moreover, additional scholars have enlightened the board capital complementarity, that concerns the level of complementarity between the directors' background and the firm activities (Zona 2013; Sarto et al. 2020).

The Board Human Capital

Focusing the attention on the human capital element of the board capital, it is worth noting that the idea of human capital finds its origin in 1960s when the economists Schultz (1961) and Becker (1962) defined and formalized the *Human Capital Theory*. Indeed, over the early 1960s, scholars of economic growth found out a number of difficulties in explaining the boost of US economy in

terms of traditional tangible factors of production (Krueger 1968). Indeed, researchers used to neglect "the residual" factors that instead were crucial determinants of the economic gap, that is, the *human capital* (Becker 1962; Schultz 1961; Weisbrod 1966). Differently, Schultz (1961) and Becker (1962) interpreted this gap through the lenses of the human capital theory. The base principle of the theory is that within an organization peoples' learning capacities are valuable as well as the other resources that are employed in the production (Lucas 1988). In this sense, if these resources are empowered through investments and are effectively used, the results are profitable not only for the individual but also for the organization and the overall society (Becker 1962; Schultz 1961). Therefore, according to the human capital theory the human capital is a crucial determinant for the organizational outcomes. Building on this assumption, as previously stated, corporate governance literature has developed the concept of human capital as a part of the wider notion of board capital (Hillman et al. 2002).

Research investigating the board human capital provides a number of classifications (Gibbons and Waldman 2004; Lester et al. 2008). Most studies distinguish between general and specific human capital. While the former includes the overall expertise that is generally applied across settings, the latter considers the one that matters for a specific firm, industry, and function (Behrens et al. 2012; Ganotakis 2010; Kor and Sundaramurthy 2008; Marvel and Lumpkin 2007). In particular, studies on general human capital focus on the director education by examining the educational qualification awarded by prestigious universities and management schools or the educational degree (e.g., PhD and master degree) (Arena et al. 2015; Bond et al. 2010; Barroso et al. 2011). As for the specific human capital, research distinguishes among firm, industry/sector, and functional expertise (Ganotakis 2010).

As generally reported for the board capital, the human capital of board members determines the board ability to effectively execute both monitoring and resources provision roles (Hillman and Dalziel 2003).

Concerning the former, having firm and industry experience/expertise allows to better know the typical management job tasks and skills useful, for example, to perform the board's duties of nominating top executives (Tian et al. 2011). Expertise in the firm or in the sector is also relevant for the management evaluation process as it fosters the better identification of appropriate activities as well as the estimation of changes to cope with future firm contexts and environments (Carpenter et al. 2001; Jensen and Meckling 1976). The assessment and the evaluation of managerial activities also benefits from the breadth of knowledge of board members. Indeed, the presence of heterogeneous board members, with a wide range of skills and expertise, allows to observe the problem from different points of view.

Concerning the second role, board human capital improves the provision of advice and counsel as well as legitimacy for firm operating activities (Hillman and Dalziel 2003).

Regarding the strategic process, literature reports that taking complex strategic decisions requires, in strict time constraints, managing information overload as well as effectively recognizing the long-term implications of the alternatives to consider (McDonald et al. 2008). In this sense, experts are generally better able to solve these troubles as they hold highly developed problem-solving skills and better knowledge of critical issues in the area where they are experts (Kor and Sundaramurthy 2008). Moreover, experiences in the same firm/industry allow them to better understand firm business, technology, human assets, and the specific setting conditions so as to overcome decision challenges (Kroll et al. 2008). Still concerning the strategic board process, the advice and counsel role of the board benefits from the presence of (e.g., educational and functional) (Bunderson and Sutcliffe 2002; Forbes and Milliken 1999; Li and Hambrick 2005). Literature in this tradition reports that the board human capital heterogeneity improves the directors' decision-making and results in positive corporate outcomes. Indeed, scholars suggest that the background diversity connected to the cognitive heterogeneity of board members stimulates the debate among directors and enhances the board

problem-solving (Lester et al. 2008; Cho and Hambrick 2006). In addition, scholars claim that the board human capital heterogeneity increases the information available to board directors, fostering the proper appraisal of company opportunities with positive implications for their decision making activity (Brodbeck et al. 2007).

Turning the attention to the provision of legitimacy, directors with relevant expertise/experience like business founders (Kor and Sundaramurthy 2008), former government members and politicians (Hillman et al. 2000; Hillman 2005; Lester et al. 2008), or generally business/industry experts (Hillman et al. 2000; Kor and Misangyi 2008), increase the reputation of both board and organization (Certo 2003; Hillman and Dalziel 2003). Moreover, the board members' educational qualification awarded by prestigious universities and management schools, or board educational level (in terms of PhD, master degree, or bachelor degree), improves the reputation of the board functioning (Arena et al. 2015; Bond et al. 2010; Barroso et al. 2011).

Empirical studies report supportive findings in this sense. As human capital enhances the effectiveness of governance roles, and as an effective governance function improves company output (Nicholson and Kiel 2004), this literature explores the relationship between industry expertise, firm expertise, functional background and heterogeneity, and the organizational outcomes.

More specifically, it is possible to highlight the existence of four main streams of research.

The first stream examines the implications of the quality of board human capital, in terms of level of expertise and experience. Studies in this tradition have investigated the implications of the educational level on the innovation (Wincent et al. 2010; Dalziel et al. 2011) and the internationalization (Barroso et al. 2011). Others have explored the effect of the educational level of board members on financial performance (Jermias and Gani 2014; Arena et al. 2015) and IPO value (Certo 2003; Sundaramurthy et al. 2014).

The second stream of research investigates the implications of having working experience in specific activities or specific functions (i.e., the functional expertise), as well as a training/education in

a specific area. More specifically, some studies have reported the implications of board financial expertise for the debt level (Burak Güner et al. 2008), strategic choices (Jensen and Zajac 2004; Westphal and Fredrickson 2001), innovation (Dalziel et al. 2011), firm performance (Kim and Lim 2010; DeFond et al. 2005), and finally, accounting practices (Dhaliwal et al. 2010). Other studies have investigated the performance implications of having expertise in specific activities and contexts such as M&A operations (McDonald et al. 2008), strategic alliances (Chen and Lai 2017), internationalized organizations (Chen et al. 2016), and green setting (Cowden and Bendickson 2015).

The third research stream is composed by articles investigating the implications of board members expertise/experience consistent with the characteristics of the company in which they have been appointed. This is the case of industry and firm expertise. Concerning the former, several articles have explored the relationship between this measure of board human capital and firm outcomes such as the start-up success (Kor and Misangyi 2008), the outcome of M&A operations (Kroll et al. 2008), the firm growth (Kor and Sundaramurthy 2008), the earnings management (Wang et al. 2015), the level of internationalization (Barroso et al. 2011; Volonté and Gantenbein 2016), the market value (Tian et al. 2011), and the firm performance (Dass et al. 2014; Veronesi et al. 2013). Turning the attention to the firm expertise, a less copious group of papers have explored the positive implications of board members with previous experiences in the same firm. They mainly investigate firm outcomes in terms of growth (Kor and Sundaramurthy 2008), internationalization (Barroso et al. 2011), and market reaction (Fahlenbrach et al. 2010).

Finally, the fourth stream of research has explored the relationship between, on the one side, the board background heterogeneity and, on the other side, the financial outcomes (Antonelli et al. 2013; Wellalage and Locke 2013; Harris and Helfat 1997; Volonté and Gantenbein 2016; Vandenbroucke et al. 2016) and the corporate innovation (Midavaine et al. 2016; Van Knippenberg

et al. 2011; Kim and Kim 2015; Bianchi et al. 2012; Sarto et al. 2020; Heyden et al. 2015).

The Board Social Capital

Shifting the attention to the other side of the coin, that is, the board social capital, literature defines it as the directors' ability to extract future economic benefits from the resources that they obtain through the established relationships with external and internal stakeholders, at board and company level (Berezinets et al. 2016).

Previous studies have identified several board social capital classifications. However, the most widespread classification distinguishes the internal social capital from the external one. The first element includes director's ties within the governing board, and refers to the relationships established among the same directors. Differently, the external capital includes the links established by board members with the external environment (inside and outside the firm), thanks to which they gain information, power, legitimacy, and other critical resources for the achievement of the firm competitive advantage (Pérez-Calero et al. 2016). In this regard, the board external social capital can be in turn divided into two sub-elements. On the one side, it refers to the relationships between board members and the manager/employees inside the firm. On the other side, it includes the links that directors create with stakeholders outside the company. Finally, it is worth noting that aside the internal and external board social capital, scholars suggest the existence of a *borderline* social capital element that can be considered either internal or external and that refers to the director's social standing and reputation (Sarto 2019).

Focusing the attention on the external board social capital, and specifically on the established links with stakeholders outside the company, scholars distinguish the single-type bonds from double-type ones. In the first case, they represent relationships that a director directly establishes with another company. This phenomenon occurs when a non-executive director sits on the board

of the “X” company and is fully employed in the “Y” company. Differently, double links occur when a board member of “X” company also sits on the board of the “Y” company and correspond to the interlocking directorship phenomenon (Johnson et al. 2012). In this regard, scholars suggest that there are a number of positive implications of the existence the above-mentioned links. Firstly, relationships allow the access to useful and timely information, fostering the information sharing. This is beneficial for board processes, and for the fulfillment of the advice and counsel role, especially with regard to the strategy formulation (Ferris et al. 2003), thus positively affecting company outcomes (Kor and Sundaramurthy 2008; Hoitash 2011; Jiraporn et al. 2008). From a different point of view, relationships with external stakeholders allow firm to access to crucial resources as well as to acquire them at more favorable conditions, with positive effects for business performance (Hillman 2005; Kor and Sundaramurthy 2008).

Still concerning the external capital, but focusing on the links among board members and manager/employees/owners of the same firm, scholars claim that these relationships can occur in three specific cases (Johnson et al. 2012). First of all, board members can be “affiliated,” as they have been appointed on the board due to previous working relationships with the firm, such as in the case of suppliers, consultants, or customers. Second, directors can be appointed on the governing body based upon a CEO’s request. Finally, there is the case of members with personal relationships with company managers, based on family or friendship links (Jones et al. 2008). Research on the topic suggest that personal and trust relationships can favor the information sharing between the board and the company, thus improving the board strategic process. Indeed, directors with friendship links are better able to express their doubts about corporate strategies (Westphal and Bednar 2005). From a different point of view, other studies document that “affiliated” directors as well as members with personal ties carries weight in the decision-making process and are more

influential compared with their peers (Stevenson and Radin 2009).

Turning the attention to the internal social capital, studies show that the links among directors are consequences of their previous work experience within the same team. In this regard, the board functioning takes advantage from the co-working experience and this positively affects company performance (Tian et al. 2011). Indeed, board members develop tacit knowledge of the firm and its characteristics, and this is especially useful for independent members. In addition, thanks to the co-working experience, the team increases its ability of coordination and integration of various skills represented in the group.

Shifting the focus on the last dimension of the board social capital, literature has highlighted the crucial role played by the directors’ social status. Indeed, research suggests that the reputation and prestige of a board member act as a signal, by increasing the external legitimacy of the firm (Certo 2003). Indeed, it is able not only to increase the overall trust of external stakeholders toward the firm, but also to allow the company access to crucial resources.

Summary

This entry illustrates the main characteristics of Board capital. More specifically, it examines in depth both the human and social dimensions of board capital, by explaining their implications for the board of directors’ effectiveness and firm outcomes.

Liverpool, UK

Synonyms

[Audit committee](#); [Board committees](#); [Board of directors](#); [Corporate governance](#); [Ethics and compliance committee](#); [Nomination committee](#); [Remuneration committee](#); [Risk committee](#)

Definition

The board of directors may establish specialized board committees to allow more in-depth focus in particular areas, thus increasing efficiency (BCBS 2015). These committees are often referred to as subcommittees and are created and mandated by the full board. There are various board subcommittees, namely nomination committee; audit committee; remuneration committee; risk committee; and ethics and compliance committee.

Nomination Committee: A subcommittee of the board of directors tasked with making recommendations to the board on appointments and succession planning.

Audit Committee: A subcommittee of the board of directors tasked with reviewing the scope and outcome of the audit function and ensuring auditor objectivity.

Remuneration Committee: A subcommittee of the board of directors tasked with making recommendations to the board on executive directors' remuneration including base salary, bonuses, stock options, pensions, and other benefits.

Risk Committee: A subcommittee of the board of directors tasked with assessing the firm's financial, operational, and reputational risk exposure.

Ethics and Compliance Committee: A subcommittee of the board of directors tasked with the responsibility of ensuring that the firm has appropriate mechanisms to promote good

Board Committees

► Board Committees and Corporate Governance

decisions and compliance with applicable legal and regulatory provisions, as well as internal rules.

Introduction

There is now clear recognition of the importance of sustainability initiatives in achieving effective corporate governance. For example, the FRC (2018) states that “a successful company is led by an effective and entrepreneurial board whose function is to promote the long-term sustainable success of the company, generate value for shareholders, and contribute to the wider society.” The board of directors is tasked with establishing the company’s purpose, strategy, and values and in ensuring that “resources are in place for the company to meet its objectives and measure performance against them and establish a framework of prudent and effective controls which enables risk to be assessed and managed” (FRC 2018). The board may appoint various subcommittees or delegate some of its role and responsibilities to committees to enhance its oversight and decision-making effectiveness (Tricker 2012; BCBS 2015). While board committees assist individual directors and the entire board to discharge duties and functions, the board of directors is ultimately responsible for the delegated duties and functions and the various subcommittee report directly to the board. (OECD 2004; The BCBS 2015; Mallin 2019).

Board committees allow the injection of increase objectivity into the decision-making process and assist the board of directors in effectively dealing with board functions by considering in greater detail than would be possible for the board as a whole (Lincoln et al. 2017). Nomination, remuneration, and audit committees are the most commonly found board committees (OECD 2004; FRC 2018). The FRC (2018) recommends that “the board should establish a nomination committee to lead the process for appointments, ensure plans are in place for orderly succession to both the board and senior management positions, and oversee the development of a diverse pipeline for succession” (FRC 2018). Furthermore, a large

preponderance of the members of the committee ought to be independent non-executive directors. The Cadbury Report (2000) recommended that an audit committee and remuneration committee should be formed and recommends a nomination committee in order to ensure the board appointment process is more transparent. The Higgs review (2003) confirms this view by reporting that most listed companies have an audit committee and a remuneration committee.

The number and nature of subcommittees established ultimately depends on company size, its board, its business, and its risk profile. To ensure transparency and accountability, a board should disclose pertinent information to the committees to enable them carry out their functions effectively and also the board should implement a term of reference that sets out the mandate, scope, working procedures, and composition of its committees (BCBS 2015). Thus, effective corporate governance mandates that the board of directors must develop a written, concise description of the roles for the board of directors, chair, CEO, and the board subcommittees. To maintain the independence of these committees, it is best practice for the board chairman not to serve simultaneously in his/her capacity as the head of the board and as a committee member. It is also best practice to ensure that no director can serve on more than two of these three committees: nomination, remuneration, and audit (BCBS 2015).

Key Issues

Nomination Committee

The FRC (2018) recommends that the board should establish a nomination committee. The nomination committee is tasked with evaluating the skills, knowledge, experience, and independence of the board, and utilizing this when preparing a candidate profile for new appointments (Tricker 2012; Hannigan 2018). The nomination committee is responsible for appointments to both the board and senior management positions. It is also tasked with overseeing the development of a diverse pipeline for succession and should identify possible gaps and challenges in the skills and

knowledge of the board (BCBS 2014; Hannigan 2018). This recommendation is important in light of the fact that boards are often criticized for being inadequate in selecting chief executive officers (CEO) (Larcker and Tayan 2011). The Spencer Stuart UK Board Index (2011) discovered that chairman succession planning is not widely discussed in most UK boards. This is because few formal mechanisms have been implemented to address the issue beyond the chairman's annual review with the senior independent nonexecutive directors. Therefore, shareholder groups have pressured boards to increase the transparency in succession plans (The Spender Stuart UK Board Index 2011). The work of the nomination committee should also be described in the annual report.

Interestingly, the FRC (2018) also reflects an emphasis on gender diversity and inclusivity, it states that "appointments and succession plans should be based on merit and objective criteria and, within this context, should promote diversity of gender, social and ethnic backgrounds, cognitive and personal strengths" (FRC 2018). As well as reporting on "policy on diversity and inclusion, its objectives and linkage to company strategy, how it has been implemented and progress on achieving the objectives and report on the gender balance of those in the senior management" (FRC 2018).

To be effective, "majority of members of the nomination committee should be independent non-executive directors with a minimum membership of three, the chair of the board should not chair the committee when it is dealing with the appointment of their successor, and the length of service of the board as a whole and membership regularly refreshed" (FRC 2018).

Audit Committee

Various national and international policy-makers have highlighted the importance of the audit committee as the bridge connecting external auditors and the board of directors (OECD 2004; BCBS 2015). The audit committee protects shareholder and other stakeholder interests by monitoring financial reports and internal control. In the aftermath of the 2007–2008 global financial crises,

audit committee members have been criticized for their lack of skills and expertise, and their intrusion in the legitimate responsibilities of executive management (Tricker 2012). Other criticisms included their proclivity for bureaucratic and rigid processes and their inability to exercise good judgment (Tricker 2012). The FRC advocates for the establishment of an audit committee. The UK also implements the European Union Audit Directive (2014/56/EU), which imposes a requirement for firms whose securities are traded on a regulated EU market to have an audit committee. This further shows the importance of the audit committee and steps taken both on a national and international level to ensure this key function within the firm.

Several national corporate governance codes recommend that audit committees should be comprised of financially literate independent non-executive directors (FRC 2018). The FRC (2018) recommends that audit committee should be comprised of independent nonexecutive directors, and there should be a minimum membership of three members and two members in the case of smaller companies. This recommendation is supported by research work carried out by Yeh et al. (2011) who found that financial firms with more independent nonexecutive directors on the audit and risk committees performed better during the 2007–2008 global crises.

The FRC (2018) notes that "the chair of the board should not be a member. The board should satisfy itself that at least one member has recent and relevant financial experience. The committee as a whole shall have competence relevant to the sector in which the company operates." Furthermore, in order to ensure collaboration in the auditing process, the audit committee should have access to external auditors for explanations and additional information without the presence of management (FRC 2018). The audit committee is tasked with a robust list of responsibilities. Principle 25 of the FRC sets out the main roles and responsibilities of the audit committee. It states that the role and responsibility of the audit committee include monitoring the integrity of the financial statements of the company and providing advice to the board on the fairness of annual

reports and accounts as well as “internal control and risk management systems including the internal audit function.” The audit committee is also tasked with recommending the board of directors the appointment and removal of external auditor, ensuring external auditor objectivity and compliance with any professional and regulatory requirements. Finally, the audit committee is tasked with devising policy where external auditors are required to provide non-auditing services and ensuring this does not encroach the auditor’s independence (FRC 2018).

Remuneration Committee

The remuneration committee is tasked with the responsibility for devising policy for executive director pay and setting pay and remuneration for the chair, executive directors, and senior management including base salary, bonuses, stock options, pensions, and other benefits (FRC 2018). National and international policy-makers highlight a clear link between remuneration and individual performance of executives and overall firm success (BCBS 2015; FRC 2018). Therefore, the role of a remuneration committee is to ensure that there is a formal and transparent procedure for developing remuneration policy and ensuring that compensation is appropriate and consistent with the organizational culture, long-term business prospects, risk strategy, and performance of the organization, appropriate legal and regulatory requirements, and promotion of long-term sustainable success of the organization (Tricker 2012; FRC 2018; Mallin 2019).

Decisions on executive remuneration packages should be made by those who do not stand to benefit directly from them. Thus, as a matter of good governance practice, executive directors should not be responsible for determining their own remuneration. The remuneration committee should comprise of a “minimum of three independent non-executive directors. In the case of a small company a minimum of two independent non-executive directors is required (FRC 2018). In addition, the chair of the board can only be a member if they were independent on appointment and cannot chair the committee. Before appointment as chair of the remuneration committee, the

appointee should have served on a remuneration committee for at least 12 months” (FRC 2018). The remuneration committee works closely with various other subcommittees. For example, the remuneration committee works with the risk committee in evaluating the incentives created by the remuneration system to ascertain whether incentives provided take into consideration risk, capital, liquidity, and the likelihood and timing of earnings (BCBS 2015). In addition, the Higgs Report (2003) recommends that the “remuneration committee work closely with the nomination committee to ensure incentives are appropriately structured for directors and for senior executives,” avoid rewarding poor performance and ensure appropriate policy is in place to deal fairly in cases where departure is not due to poor performance.

Recent legislative development in this area includes the Companies (Miscellaneous Reporting) Regulations 2018 which require publication and justification of the companies pay ratio and also “illustrate the effect of future share price increases on executive pay outcomes” in order to ensure shareholders are clearly informed when voting on long-term incentive plans. For the first time, quoted and UK registered companies with more than 250 UK employees are now legally mandated to publish and justify the pay difference between chief executives and their staff on an annual basis. The obligations now imposed on these companies are to be expected in light of the fact that excessive remuneration and lack of proper transparency and accountability vis-à-vis remuneration were some of the catalysts in the recent financial crisis. For example, Bebchuk et al. (2010) found that excessive remuneration for executives at US Bear Stearns and Lehman Brothers encouraged a culture of excessive risk-taking in 2000–2008. In the aftermath of the 2007–2008 financial crises, the OECD (2004) discovered that remuneration systems failed worldwide because managers had considerable influence over the level and conditions for performance-based compensation, which meant that boards were unable to exercise objective and independent judgment. Additionally, there is evidence to suggest that the remuneration packages

of senior management in banks, in the period leading to the 2007–2008 financial crises, supported a culture where poor standards became norm (Lincoln and Adedoyin 2018).

Risk Committee

Various governance codes and guidelines recommend the establishment of a risk committee, comprised of independent nonexecutive directors who are financially knowledgeable, charged with the responsibility of advising the board on current and future risk strategies, and overseeing the implementation of such strategies by senior management (BCBS 2010; FRC 2018). Risk management subcommittee provides “strategies for capital and liquidity management, as well as credit, market, operational, compliance, reputational and other risks of the company.” It is argued that the creation of a risk committee will circumvent the widespread failure of risk management discovered in the aftermath of the 2007–2008 financial crises. For example, in the aftermath of the 2007–2008 global financial crises, the OECD (2004) found that boards of directors were still ignorant of the risk’s firms encounter. It therefore reaffirmed the need to ensure that effective risk management is established in firms. However, in some listed firms risk assessment is imbibed in the mandate of the audit committees. For example, in the USA, the NYSE’s listing rules mandates the audit committee with the task of explaining the risk assessment and management policies of listed firms. This creates additional problems and complexities because audit committees examine the past to discharge their accountability functions. They are involved with audit outcomes and provide accountability information for financial reports (Tricker 2012). As risk assessment needs to be forward-looking, the audit committee may not be ideal for such responsibilities (Lincoln and Adedoyin 2018).

The presence of a risk management committee cannot be overstated particularly in certain sectors for example the banking and financial sectors. This view is also supported by the BCBS (2010) and the FRC which emphasizes that the nature and business of banking dictates for the inclusion of a risk committee among board subcommittees

(BCBS 2010; FRC 2018). In addition, Yatim (2010) found a significant correlation between the presence of a risk management committee and strong board structures.

Ethics and Compliance Committee

The OECD (2004) recommended that firms set up internal programs and procedures to promote compliance with applicable law, regulations, and ethical standards. The BCBS (2010) states that the ethics and compliance committee should ensure that the organization has the appropriate mechanisms to promote good decisions and compliance with applicable legal and regulatory provisions, as well as internal rules. This is important to the corporate governance agenda and the spirit of corporate governance recommendations which mandates that firms act in a moral and ethical manner (Mallin 2019). According to Stevens et al. (2005) the extent to which ethics codes are used by executives when making strategic choices is unknown. That said, executives were observed to be more likely to integrate their firm’s ethics code into their decision-making process where there is perceived pressure from various stakeholder groups. In addition, it was found that ethics codes create an internal ethical culture and promotes a positive external image of the firm and that they are integrated into daily activities through training programs. The importance of the ethics and compliance committee and their role in ensuring the implementation of appropriate internal ethical and compliance programs and procedure cannot be overemphasized. Creation of an ethics committee helps ensure that shareholders rights are protected, checks and balances are in place to help detect and prevent fraudulent behavior, and that the rule of law is upheld (Lincoln et al. 2017).

Summary

Board committees are an integral part of the internal corporate governance mechanism ensuring effective and efficient dispatch of the boards business by considering it in more detail than would be convenient for the whole board.

Board committees allow the injection of objectivity in the decision-making process. Various board committees include nomination committee; audit committee; remuneration committee; risk committee; and ethics and compliance committee. The increased use of board committees in recent times has played an important role in raising corporate governance standards worldwide. It is incumbent on all directors to act in the interest of the company, that said, the board committee also have a particular role to act independently of the executive in ensuring that shareholders' interests and various stakeholder groups are properly protected in relation to the stated objective of the subcommittee and the role for which it was set up to fulfill. However, the board retains ultimate responsibility, thus disagreements within the board, as well as disagreements involving various board committee's members and the board as a whole, are resolved predominantly at board level.

Board "committees give assurance that important board duties are being rigorously and diligently discharged." In order to be effective however, various corporate governance codes and guidelines provide that nonexecutive directors, and independent non-executive directors, should play leading roles in these board committees. The rationale behind this is that the inclusion of independent nonexecutive directors helps to avoid conflict of interest for the executive directors. Finally, it is crucial when appointing committee members that the board draws on those nonexecutive directors and independent non-executive directors who possess relevant skills and expertise. This allows the committees to comprehensively understand their role and responsibilities, objectively evaluate outcomes to be achieved and bring fresh thinking to decision making.

Board Diversity and Gender Quotas

[Board heterogeneity](#)

Definition

Board diversity refers to the “board composition and the varied combination of attributes, characteristics and expertise contributed by individual board members in relation to board process and decision making” (van der Walt and Ingley 2003, p. 219). Gender is the most relevant feature that may drive board diversity. As a matter of fact, different countries are introducing regulations promoting the appointment of female directors to boards with the purpose of fighting gender inequality in top corporate positions.

Introduction

Board of directors’ diversity is a broad concept that refers to the “board composition and the varied combination of attributes, characteristics and expertise contributed by individual board members in relation to board process and decision making” (van der Walt and Ingley 2003, p. 219). This definition emphasizes two relevant aspects of board diversity: (i) the antecedents of diversity and (ii) its effect (Rao and Tilt 2016). Board

diversity is a multidimensional concept driven by distinct individual director attributes; some are observable (e.g., gender, age, race, or nationality) while others are less apparent (e.g., experience, functional background or education) (Kang et al. 2007; Pelled 1996). Board diversity may affect the operation and dynamics of boards, thereby influencing performance in monitoring and advisory tasks. In line with resource dependence theory (Pfeffer and Salancik 1978), board diversity represents a source for creativity, innovation, and original solutions to problems (Carter et al. 2003; Huse et al. 2009). Directors of diverse backgrounds, knowledge, and skills might contribute to the strategic advisory role of boards by fostering different perspectives (Harjoto et al. 2015; Shaukat et al. 2016). However, it is important to balance the presence of diversity in the board given that too much heterogeneity among directors could lead to conflict and may result in the obstruction of consensus and deterioration of the board decision-making process (Lau and Murnighan 1998; Harjoto et al. 2015).

By means of its influence on board tasks, board diversity is an important determinant of firm performance in both financial and corporate social responsibility (Rao and Tilt 2016). Boards of directors are an important determinant of CSR practices given that one of their duties is to provide management with strategic advice (Jamali et al. 2008). By broadening the perspectives and backgrounds in the boardroom, diversity fosters the sensitivity of the board toward all stakeholders, not just toward shareholders (Harjoto et al. 2015; Rao and Tilt 2016).

Nowadays, the presence of female directors is the attribute most subject to attention among the different demographic characteristics that could lead to diversity. Gender inequality in top corporate positions is a global issue. This issue is particularly relevant when analyzing board of directors because women are significantly underrepresented as compared to their male peers (Terjesen et al. 2015). Female directors are more likely to be on boards in countries with more females in top management, a lower gender pay gap and a lower presence of women in political positions (Terjesen and Singh 2008). In addition,

the representation of female directors is greater at family firms, where they are usually appointed for simply being part of the family (Terjesen et al. 2015).

The overall smaller presence of women on boards is driven by a gender-stereotype effect in the board recruitment process. Women consistently face greater difficulties than men in achieving top level positions due to a “glass ceiling” effect. This term refers to invisible barriers impeding the promotion of women within organizations. These barriers are linked to an unjustified social belief claiming that women lack the adequate human capital in terms of skills, experience, and background to properly undertake upper-echelon positions (Powell 1999). The similarity-attraction paradigm (Byrne 1971) and homosocial reproduction theory (Daily and Dalton 1995) also suggest that individuals are more comfortable working with people akin to them (Byrne 1971). Thus, CEOs and current directors, mostly men, are more likely to support the appointment of new male directors (Terjesen et al. 2009). Women are required to possess greater skills and abilities to attain the same board position. The lack of transparency in director recruitment and appointment has contributed to maintaining biased and inadequate selection procedures.

Gender inequality is undesirable because it represents an ethical and moral problem; it restricts the access of women to the boardroom. Furthermore, it creates problems for firm effectiveness because they do not exploit talent from the pool of suitable director/management candidates (Terjesen et al. 2015; Terjesen and Sealy 2016). Thus we may observe a growing social and governmental demand to increase female participation in top-level positions, especially on boards of directors. Some countries, especially in Europe, have responded to this demand by proposing several instruments to promote/encourage the appointment of female directors.

Gender diversity has become an important topic of debate subject to growing public attention. This relevance has given way to a significant line of research that studies the antecedents, motivations, and consequences of the presence of women on boards and gender quotas. The papers

of Terjesen and coauthors on these issues, quoted throughout the text, help to understand these phenomena.

Instruments to Promote the Presence of Women on Boards

Two types of instruments are currently being used to increase the representation of women on boards of directors. Some governments are advocating soft law regulation by proposing voluntary mechanisms while others have decided to establish hard law regulation through mandatory mechanisms (Terjesen et al. 2015). The most common measure among the voluntary instruments is the inclusion of recommendations on board gender equality in national corporate governance codes (e.g., Australia, Austria, Denmark, Germany, Ireland, Luxembourg, Malawi, Malaysia, The Netherlands, Nigeria, Poland, South Africa, Sweden, United Kingdom, and the United States) (Terjesen et al. 2015). Some of these codes set a voluntary target for the proportion of female board members. In contrast to this approach, others simply highlight the importance of fighting gender inequality and the need to appoint female directors. The recommendations usually follow the “comply or explain” principle: firms must indicate whether they comply with the gender recommendation and explain why if they fail to do so. In addition to corporate governance code recommendations, other voluntary mechanisms are available, for example, proposed training and mentoring programs, awards for gender-balanced companies, or the creation of databases on qualified women for board positions (European Union 2013).

Regarding the legal mechanisms, some countries set mandatory quotas so that women must represent a specific proportion of board members. Companies are required to meet the quota and may face sanctions if they refuse to do so. The specific requirements of the quotas vary from one country to another. For instance, targeted firms could be state-owned, public, or both. The required proportion of women also differs significantly. It goes from the presence of at least one female director in India and United Arab Emirates

to 50% in Quebec (Canada) and Austria. The timetable for the quota implementation and the sanctions for firms also vary. In Norway, penalties are strict, even leading to firms being delisted or dissolved. By contrast, Spain prescribes no sanctions. The Spanish government tries to incentivize compliance with the quota by providing benefits to complying firms. In Italy, penalties become stricter the longer the company fails to comply; they may even result in the annulment of the board of directors.

European continental countries are more likely to establish board gender quotas. According to Terjesen et al. (2015), countries with quotas are usually characterized by three institutional factors. Quotas are more likely in countries with more policy welfare provisions, a left-party government, and a history/record of numerous initiatives fostering gender equality at the political and corporate levels.

The European Union advocates the establishment of gender quotas on boards of directors. The European Commission submitted a proposal for a directive on board gender equality in 2012. The proposed directive states that the underrepresented sex should account for 40% of nonexecutive directors at listed companies. Firms may also comply with the directive if the underrepresented sex represents at least one-third of all board members. The deadline for attaining this target is 2020. The proposal considers sanctions, such as administrative fines or the annulment of the appointment of directors, if companies fail to achieve the 40% goal/target. Although the proposal is currently under study, the European Parliament has already claimed its support for the directive, but some member countries are against establishing binding quotas.

Motivations for Establishing Board Gender Quotas

Proponents base their justification for establishing board gender quotas on two types of arguments: (i) a quest for justice and (ii) a potential positive effect on company performance. The first type of reasoning, justice, is grounded on the access of

men and women alike to the same positions. The Article 2 of the Universal Declaration of Human Rights states that no distinction should be made among human beings based on sex. However, as abovementioned, the presence of significant differences between genders in access to jobs is owed to the fact that women face stronger barriers to access top level decision-making position in firms than do men (Terjesen et al. 2009). As a minority group, women require higher qualifications to overcome discrimination stereotypes for a directorship (Hillman et al. 2002). Board gender quotas help to achieve equality by promoting the underrepresented sex to make an equitable distribution of top-level corporate positions. Increasing female representation on boards contributes to “building more inclusive and fairer business institutions that better reflect their present generation of stakeholders” (Terjesen et al. 2009, p. 320).

The second type of reasoning argues that the presence of women on boards enhances the performance of firms (Terjesen and Sealy 2016). By considering women in selection procedures and appointing them to board, firms effectively utilize the pool of human capital and hire the most talented individuals. If this is properly done, the presence of women increases the diversity of skills and abilities in the boardroom and contributes to the board decision-making process. Women are different to men in terms of backgrounds, experience, and personalities (Huse 2008; Terjesen et al. 2009). Furthermore, female directors also improve knowledge because they usually hold higher academic qualifications and broader international experience than their male counterparts (Singh et al. 2008). The diverse set of individual member attributes and characteristics fosters innovation, creativity, and the problem-solving capacity of the board as a whole. These enhancements to the board’s decision-making process ultimately lead to improved financial performance. Female presence is also likely to improve CSR performance because women are more sensitive to all of the stakeholders’ concerns (Terjesen et al. 2009). Nonetheless, female directors may feel constrained and may be reluctant to express their opinions (Terjesen et al. 2009). Thus, the positive effects provided by women may not

take place unless a critical mass of them is represented on the board (Konrad et al. 2008). Establishing gender quotas helps to achieve this critical mass of women and thereby leverage this positive impact.

Finally, board gender quotas are expected to have a spillover effect and increase female presence at all company levels as well as in the economy. They may also help to reduce the gender-pay gap. What is more, female directors may motivate other women to access management jobs (Bilimoria and Wheeler 2000).

Are Quotas Achieving Their Expected Goals?

Quotas are useful instruments for increasing the number of females, especially as compared to nonbinding measures like recommendations on corporate governance codes directors (Walby and Armstrong 2012). However, the presence of women on boards of directors is still low (Terjesen et al. 2015). Despite the improvements they have driven, quotas fall short of being effective to adequately increase female board representation. The severity of the noncompliance sanctions established by the country issuing the quota seems to partly determine the achievement of the target. For instance, sanctions in Norway are hard, and they could eventually lead to the dissolution of the company. Thus, the majority of the Norwegian companies affected by quotas achieved the 40% target. By contrast, many Spanish firms do not meet the same 40% threshold suggested by their national quota. Spain follows an incentive approach with no particular sanctions for companies failing to meet the quota.

Whether or not the representation target is met, several issues question the suitability of legally imposing board gender quotas. Although gender inequality on boardrooms is undesirable, quotas may raise ethical tensions because they try to “prevent discrimination by utilizing discrimination” (Terjesen and Sealy 2016, p. 33). The establishment of a quota might bias the selection procedure for new directors as firms may have to hire women to meet the quota regardless of their

qualifications (Terjesen et al. 2015). In so doing, quotas reduce the freedom of companies and their owners to select the most suitable individual. As a consequence, newly appointed women could feel their nomination is less legitimate because they may have been hired for firm compliance rather than for their actual merits (Sealy 2010). Nonetheless, after the quota is met, women consider they really improve the performance of the board because they are more qualified than former male directors (Terjesen and Sealy 2016).

Another problem relates to the scope of the quota. The change led by quotas is quite limited because, as Terjesen et al. (2015) noted, most of these quotas only affect listed and state-owned firms, while most companies are private. Additionally, quotas fail to increase the pool of women candidates when analyzing new board appointments because same women are actually appointed on different boards. This group of women is known as the “golden skirts” (Huse 2011).

Finally, it is noteworthy to point out that quotas could also create organizational problems, particularly for multinational companies. They could create market barriers because the voluntary or mandatory nature of female board representation may vary among countries in function of the targeted firms and fixed proportion (Walby and Armstrong 2012).

To conclude, even though quotas help to increase the presence of women on boards, they still present some inefficiencies making their suitability questionable. They should therefore be combined with other mechanisms that contribute to promoting female representation. To this respect it seems crucial to establish instruments to fight/break the barriers impeding/hindering the access of women to top level positions in the first place. Gender equality can only be effectively achieved by diminishing the cultural and environmental factors obstructing the absence of discrimination in the job market.

Summary

This chapter covers the topic of board diversity, with a particular focus on gender diversity. After

introducing the concept of board diversity, the chapter explains the main instruments that are used to promote the presence of female directors on boards. In the last sections, the application of gender quotas is briefly analyzed to characterize their situation and evaluate their influence on board female representation.

Board Diversity and Inclusivity

Adebimpe Lincoln
Law School, University of Liverpool,
Liverpool, UK

Synonyms

Board of Directors, BOD; Diversity; Equality; Gender discrimination; Inclusivity; Race discrimination

Definition

The Board of Directors (BODs) is an internal governance mechanism. The BODs are responsible for safeguarding shareholders and providing the framework which ensures alignment of management interest and those of stakeholder groups (OECD 2004; FRC 2018). As a result of the significant role played by BODs, board diversity and inclusivity are key governance issue in recent times.

Diversity in the boardroom requires an inclusion of different types of people within the organization. Inclusivity on the other hand has a much wider implication, in that, it involves including different types of people within the organization and working effectively to treat them all in an equal and fair manner (Lincoln and Adedoyin 2012a, b).

It is not enough to just have a diverse board. From a legal standpoint, steps must be taken to ensure inclusivity (Equalities Act, 2010) within boardrooms. Inclusivity celebrates the differences in each board member and requires the creation of a culture where trust, candor, and respect are celebrated as key organization objectives. In addition, inclusivity dictates that each member of the board is encouraged to contribute their experience, perspectives, and are not afraid to showcase their identity. Inclusivity promotes a culture of power sharing regardless of a person's personal characteristics and ensures that each

member is equally engaged and invested in the objectives to be achieved (Lincoln and Adedoyin 2012a, b).

Consequently, the board of directors, as the decision-making organ at the highest level of organizational leadership, play a crucial role in creating a culture and an environment that supports equality, promotes integrity and openness, and values diversity and inclusivity. There are benefits in ensuring BODs are diverse and inclusive. Diversity and inclusivity increase firm financial performance and widens the company's talent pool, thereby bolstering creativity and innovation and enabling the company to combine social justice and competitive advantage (Carter et al. 2008; House of Common's BEIS Committee Report 2017).

Introduction

Good corporate governance mandates the creation of an effective internal control mechanism within organizations. Good corporate governance also provides the framework and "structure through which the objectives of the company are set, the means of attaining those objectives" and creation of tools to effectively monitor subsequent performance (Lincoln and Adedoyin 2012a, b; OECD 2004). Furthermore, good corporate governance highlights the importance of the BODs and the role played by the board of directors as the strategic organ of the company. An effective and functional board is essential to ensure organizational success, good corporate governance, and investor relations (Lincoln and Adedoyin 2012a, b; Mallin 2019).

Lincoln and Adedoyin (2012a, b) identify the importance of the board of directors where they state that the board is "tasked with determining the company's aims and objectives and putting in place strategic plans and policies needed to fulfil those aims. The role of the board also involves leading and controlling the company and providing entrepreneurial leadership within a framework of prudent and effective controls which allows for apt assessment and management of risk" (Lincoln and Adedoyin 2012a, b; FRC 2018). According to

Epstein and Roy (2006) high performing corporate boards must seek to achieve three core objectives namely:

1. Strategic leadership for overall organizational growth
2. Transparency and accountability to various stakeholders' groups
3. Creation of qualified executive and management teams (Epstein and Roy 2006)

As a result of the 2007 financial crisis core governance issues such as diverse and inclusive boards, board evaluation, and succession planning are recognized as essential in ensuring board effectiveness. Board diversity and inclusivity allows an organization strengthen board deliberations and decision-making, thus ensuring greater injection of skills and talents into the workplace. "Individuals from different ethnicity, background and cultures bring additional and invaluable insights into the boardroom and reduces the likelihood of a 'group think' mentality forming" (Davies Report 2011; Lincoln and Adedoyin 2012a, b). Furthermore, there is consensus in the academic literature to support the view that a diverse board reflects the real-world reality as companies have a diverse set of clients, customers, and stakeholders. The need to ensure a diverse and inclusive work force is also enshrined in law. The Equalities Act (2010) mandates diversity and an inclusive approach in employment relationships. It identifies Eight protected personal characteristics, namely, disability, age, race, gender reassignment, religious belief, marriage and civil partnership, and sexual orientation.

Age

Section 5 of the Equalities Act (2010) states that "a reference to a person of a particular age group and persons who share a protected characteristic is a reference to persons of the same age group. Furthermore, reference to an age group is a reference to a group of persons defined by reference to age, whether by reference to a particular age or an age range."

Disability

According to Section 6 of the Equalities Act (2010) "a person has a disability if he/she has a physical or mental impairment and said impairment has a substantial and long-term adverse effect on his/her ability to carry out normal day-to-day activities. Reference to a person who has/or persons who share a particular protected characteristic is a reference to a person(s) who has/have the same disability."

Gender Reassignment

Under Section 7 of the Equalities Act (2010) "gender reassignment is recognised as a protected characteristic. Thus, if a person is proposing to undergo, is undergoing or has undergone a process (or part of a process) for the purpose of reassigning the person's sex by changing physiological or other attributes of sex," the person has the protected characteristic. Transsexual persons are also protected under this section.

Marriage and Civil Partnership

A "married person or a person in a civil partnership is a protected class. Consequently, any reference to a person(s) who is/are married or is/are in a civil partnership is a reference to a protected class" (Section 8 of the Equalities Act, 2010).

Race

The Equalities Act (2010) states that a racial group is a class or group of persons defined according to their race. Multiplicity of racial origin does not prevent it constituting a particular racial group. Thus, a racial group may comprise of two or more distinct racial groups. Race is said to include color, nationality, ethnicity, or national origin (Section 9 of the Equalities Act, 2010). Consequently, "a reference to a person who has a particular protected characteristic or a person's racial group is a reference to a person of a particular racial group or reference to a racial group into which the person falls."

Religion or Belief

According to Section 10 of the Equalities Act (2010) religion incorporates both religion and "reference to a religion or a lack of religion. Belief

on the other hand means any religious or philosophical belief and a lack of belief. Accordingly, a reference to a person(s) who has or shares a protected characteristic is a reference to a person(s) of a particular religion or belief or who are of the same religion or belief.”

Sex

Under Section 11 of the Equalities Act 2010, a person is afforded protection on the ground of sex. “A reference to a person who has a particular protected characteristic under Section 11 is a reference to a man or to a woman and a reference to persons who share a protected characteristic is a reference to persons of the same sex.”

Sexual Orientation

Under Section 12 of the Equalities Act (2010) sexual orientation is defined to include “a person’s sexual orientation towards a person of the same sex, opposite sex, or persons of either sex.”

Key Issues

The UK Corporate Governance Code empowers the nomination committee to develop a diverse pipeline of talent and to ensure that appointment and succession plans promote diversity (FRC 2018). According to the FRC (2018), the board of directors should strive to encourage diverse skill sets, knowledge, and experience. Thus, board appointments must be based on merit and objective criteria should be developed which ensures transparent and rigorous appointment of candidates. Selection of members for board appointments should promote various aspects of diversity, for example, cognitive and intellectual prowess, ethnicity, gender, and diverse social background (FRC 2018). In addition, an effective succession plan must be developed for senior members of the management and leadership teams.

Race and Gender Diversity and Inclusivity

Diversity is often defined broadly in terms of gender or race (Mallin 2019). Race in this context

also includes color, nationality, ethnicity, or national origin. (Mallin 2019). There is copious literature on the lack of board diversity and inclusivity vis-a-vis gender and race. For example, a study carried out by Guest (2016) found that minority executives as a whole were not afforded equal treatment when compared to their peers. The minority executives experienced lower promotion, higher demotion, and higher exit from the organization.

There is now increased focus on race diversity, prompted by the 2017 Parker Review. The Parker Review (2017) reported that there was a lack of diversity and representation of minority groups in boardrooms. The Review highlighted several issues that require improvement. For example, the need to ensure more ethnic diversity within UK boards; succession planning, enhanced transparency, and disclosure and development of skilled candidates for succession (Mallin 2019). The main finding was that there was no “director of colour” in 51 of the FTSE 100 companies as of July 2017 (Parker Review 2017; Hannigan 2018) and thus the Review made the following key recommendations:

1. “FTSE 100 board should have at least one director of colour by 2021”
2. “FTSE 250 board should have at least one director of colour by 2024”
3. “Transparency of annual reports and the need for companies to describe actions taken to increase ethnic minority diversity” (Parker Review 2017).

The contributions made by the Parker Review is a step in the right direction, as there is credible evidence to suggest that a diverse board comprised of people from different race and ethnicity perform better than boards comprised of those who share similar personal characteristics. Various Reports highlight the importance of promoting diversity and inclusivity within boards. For example, the Tyson Report (2003) states that diversity helps reduce nepotism, promotes fairness, and stakeholder engagement in corporate decision-making.

There are similar results where gender diversity is concerned. For example, the Davies Report (2011) found that women were underrepresented in boardrooms. The Report recommended that “FTSE 100 boards should aim for a minimum of 25 per cent female representation by the end of 2015,” a figure which was achieved (Davies Report 2015). In ensuring more women representation in senior executive and leadership positions, the Hampton-Alexander review (2017) increased the target to 33 % for FTSE 350 boards and 33 % for FTSE 100 by 2020. The Equality and Human Rights Commission suggests the target should be raised to 50 % (Hannigan 2018; Mallin 2019).

Various countries have also introduced forms of positive action, legislations, and quotas with a view to increasing the number of women in leadership positions (Davies Report 2011). According to Lincoln and Adedoyin (2012a, b), the need for increased participation and representation of women stems from the unique role women play. “Women are independent and possess a better understanding of consumer behaviour and opportunities to meet those needs, this is because women make around 70 percent of consumer purchasing decisions as such being able to connect better with the female workforce and consumer base affords more opportunities for companies to be able to better understand their customer base and drivers of the decision-making process. Various writers suggest that having women in top management can result in higher earnings and greater shareholder wealth and better corporate governance and increased competitive advantage” (Lincoln and Adedoyin 2012a, b).

Research in the UK supports inclusion of more women in leadership positions and in the board room. Carter et al. (2008) asserts that the presence of women in leadership positions and in board of directors results in “improved performance of Fortune 500 companies, primarily through the effect on the boards audit function.” This is because of the fact that “women are shown to pay more attention to monitoring firms and appear to be better at explicitly identifying criteria for measuring and monitoring the implementation of corporate strategy when compared to an all-male

board. In addition, women play a more active role in setting the strategic direction and weighing long-term priorities of the company. The main impact includes increased attendance and better board monitoring and increased diversity in the company’s top management team” (Lincoln and Adedoyin 2012a, b; World Development Report 2012). Research also shows that “having at least one female on the board of directors helps reduce the risk of bankruptcy, enhance accountability and ensure more effective communication between the board and stakeholders” (Wilson and Altanlar 2009; Lincoln and Adedoyin 2012a, b).

Board diversity and inclusivity shows a declaration for equality and a policy for non-discrimination on grounds of a protected characteristics, thus promoting a commitment which ensures people are not disenfranchised and subjugated. Achieving board diversity is not without its challenges. For example, Lincoln and Adedoyin (2012a, b) notes that “coordination may be difficult and costly to attain, consequently potential increase in performance may not be adequate to balance the increased associated costs. Other arguments against board diversity include less efficient decision-making ability, which affect the firm’s ability to compete effectively. Some scholars argued that actively seeking board diversity can be damaging to board cohesion.” Other challenges identified in extant academic debates include increase conflict where there is race, ethnicity, and gender diversity, which results in reduced performance and lack of communication thereby reducing group cohesion (Lincoln and Adedoyin 2012a, b). Notwithstanding the challenges, there is a case to be made for board diversity and inclusivity, a diverse board is one with the right composition of members, equipped with requisite skill and experience needed to make strategic decision and implement long-term vision for organizational survival and growth.

Summary

Board diversity and inclusivity are key determinant of effective corporate governance. Board

diversity encourages better corporate governance, transparency, and effective stakeholder management. Lack of board diversity and inclusivity has a wider impact on the dynamics of the board, firm performance, governance, and social responsibility.

A legal case for diversity and inclusivity is as a result of the fact that it is enshrined in legislation that a person should not be discriminated against on the basis of his or her personal characteristic. For example, the UK Equalities Act 2010 which was enacted to reduce socioeconomic inequalities and increase equality of opportunity for all, prohibits discrimination on grounds of gender, race, ethnicity, religion, age, disability, and sexual orientation.

In addition, there is a conceptual argument for promoting a diverse and inclusive board. The conceptual case stems from the need for a more nuanced understanding of dynamism inherent in an increasingly varied organizational context. Thus, the inclusion of people from diverse backgrounds allows for a more robust awareness of intricacies both within the work environment and on a global scale, thereby ensuring broader perspectives are considered when making decisions, and that there is a genuine attempt at cultural integration and creation of effective global networks.

The reality is that many boardrooms do not reflect gender, race, or ethnic diversity; are not inclusive nor do they reflect the stakeholder groups that the companies engage with. Consequently, it is imperative to continue to ensure annual evaluation of boards to monitor their composition, to ensure they are diverse and inclusive, while also ensuring that the board can work together effectively in order to achieve set objectives. Furthermore, organizations policy on diversity and inclusivity must meet the objectives set out in various corporate governance codes and government reviews targeted toward achieving greater board diversity and inclusivity.

Definition

The board of directors is the beacon of the company, tasked with the responsibility for postulating the firm's strategic vision, ensuring transparency and accountability to shareholders and stakeholders. A significant difference between countries is the type of board. Boards can either be "unitary" or "dual" depending on the country.

The unitary board, commonly referred to as the one-tier board, is characterized by one single board, comprising both executive and non-executive directors. Unitary boards are charged with the overall responsibility of monitoring management and determining and implementing the strategy of firms. Unitary boards are vested with the responsibility for all aspects of the company's activities. Shareholders elect directors to the board at the company's annual general meeting (AGM), and all the directors work to achieve the same ends (Mallin 2019). Unitary boards are prevalent in Anglo-Saxon countries such as the United States, Australia, and New Zealand (Mallin 2019).

The dual board, commonly referred to as two-tier board, is the prevalent type of board worldwide. Dual boards are widespread in countries such as Austria, Denmark, and Germany (Mallin 2019). A dual board system consists of a supervisory board and an executive board of management. The supervisory board oversees the

direction of the firm and as such is comprised entirely of nonexecutive directors who are appointed by shareholders and other stakeholders. The management board is tasked with the running of the firm and is composed entirely of executive directors who are appointed by the supervisory board to run the firm (Mallin 2019).

Introduction

Ultimately, the board of directors' paramount responsibility is to ensure positive performance of the firm and maximize wealth for its shareholders. In recent times, this responsibility has been extended to cater for a variety of stakeholder groups. Consequently, the board of directors is also tasked with aligning the firm's objectives with the stakeholder's expectations. Effective corporate governance mandates a hierarchy of accountability of the firm to various stakeholders. The board provides entrepreneurial, strategic, and ethical leadership to the firm and ensures that management is acting in the best interests of owners and other stakeholders through the board's advisory and monitoring roles, thus enhancing and sustaining the prosperity of the firm. This assertion is also echoed by the UK Corporate Governance Code which states that "a successful company is led by an effective and entrepreneurial board, whose role it is to promote the long-term sustainable success of the company, generating value for shareholders and contributing to wider society" (Financial Reporting Council 2018). To this end, "the board should establish the purpose of the company, its core strategy and cultural values and ensure clear alignment." In addition, company directors must strive to act with integrity and promote organizational culture through effective leadership. The company should also ensure that it provides required resources for the company to meet its objectives. Finally, effective control mechanisms should be established to cater for assessment of risk and encourage shareholder and stakeholder participation (Financial Reporting Council 2018).

There is synergy therefore with the "Enlightened Shareholder Value" concept enshrined into

UK company law legislation by virtue of Section 172 of the Companies Act 2006, "the Board of Director is expected to understand the views of the company's other key stakeholders and describe in the annual report how their interests and the matters set out in section 172 of the Companies Act 2006 have been considered in board discussions and decision-making." Accordingly, Section 172 of the Companies Act (2006) states that the director in promoting the success of the company should: "act in the way he considers, in good faith, would be most likely to promote the success of the company for the benefit of its members as a whole, and in doing so have regard to:

- (a) the likely consequences of any decision in the long term,
- (b) the interests of the company's employees,
- (c) the need to foster the company's firm relationships with suppliers, customers and others,
- (d) the impact of the company's operations on the community and the environment,
- (e) the desirability of the company maintaining a reputation for high standards of firm conduct,
- (f) the need to act fairly as between members of the company."

Key Issues

The role and responsibilities of the board of directors in countries around the globe is contained in various corporate governance codes and guidelines. The board of directors is tasked with the responsibility of implementing the guidelines and principles contained therein. For example, the UK Corporate Governance Code (2018) contains a set of principles which highlight the "importance of good corporate governance to long-term sustainable success."

Board Leadership and Division of Responsibilities

A well-balanced, independent, and qualified board is essential to corporate governance as composition has a direct impact on corporate performance. The board of directors is led by the "Chairman" who is responsible for the overall

direction and effectiveness of the firm, setting board agenda, overseeing hiring, firing, and evaluating chief executive officer remuneration (Tricker 2012). The chair should seek to demonstrate objective judgement throughout their tenure in office and promote a culture of openness and debate. The importance of the position of the chair can also be seen when one considers their role in facilitating board relations, effective contribution of all nonexecutive directors, and provision of accurate, timely, and clear information to directors.

The chief executive officer (CEO) is the “single most influential individual responsible for the overall management” and performance of firms (Mallin 2019). The majority of academics and policy-makers favor CEO and chairman separation as they argue it ensures checks and balances, enhances board independence and accountability, and reduces potential conflict of interests (OECD 2004; Mallin 2019). Several countries including Australia, Belgium, Canada, France, Germany, Italy, Japan, Sweden, Switzerland, the Netherlands, and the United Kingdom advocate for the separation of roles. For example, the UK Corporate Governance Code states that the roles of chair and chief executive should be held by separate individuals. In exceptional circumstances, where duality be favored, this should be proposed by the board, and major shareholders should be consulted ahead of appointment. Furthermore, the board should provide a clear rationale to shareholders at the time of the appointment. This information should also be provided on the company website (Financial Reporting Council 2018).

The promoters of the two main governance theories also call for separation of the roles. Agency theorists argue that the position of chairman and CEO should not be held by the same person. The reasoning here is that separation of the roles is said to dilute the power of the CEO thus enabling the board to properly exercise independent judgment and critically evaluate CEO and management performance (Jensen 1993). Stakeholder theorists assert that duality hinders the stakeholder orientation of directors. Thus, duality is seen to provide an individual with immeasurable powers, including the authority to

establish strategic influences. Such power and influence can intimidate other directors and restrict stakeholder orientation in firms (Lincoln et al. 2013).

The board is supported by the office of the company secretary. The company secretary advises the board on all corporate governance matters. The company secretary must act in good faith and avoid conflict of interest (Mallin 2019). Furthermore, the company secretary ensures that the board and relevant board subcommittees are equipped with requisite information and resources to function effectively. Directors require accurate, relevant, timely, and continuous information regarding internal and external environment of firms (OECD 2004; Tricker 2012). Such information should include firms’ industry, competitors, customers, products, operations, financial position, and the overall political, economic, social, and technological environment.

Nonexecutive directors (NEDs) and independent nonexecutive directors (INEDs) play a prominent role in the corporate governance agenda. There is growing consensus in corporate governance literature that the board of directors should be comprised of a sufficient number of NEDs and INEDs to ensure that it can exercise independent judgment of corporate affairs (OECD 2004; BCBS 2010). NEDs are directors who do not hold executive management position in firms; they act as a control mechanism of executive directors by ensuring that no individual or group can unduly influence board of directors’ decisions (Mallin 2019). NEDs help in minimizing conflict of interest among stakeholders, particularly between shareholders and regulators, and contribute to the overall leadership and competitiveness of the firm (Mallin 2019). That said, their ability to effectively execute their responsibilities depends on NEDs having sufficient time and possessing the appropriate knowledge and skills to be effective. Additionally, the effectiveness of NEDs is dependent on information symmetry between executive directors and NEDs. Therefore, various national codes and international principles recommend that NEDs must be supplied with necessary information in a timely manner. INEDs, on the other hand, are directors with no affiliation or

relationship with firms, who can exercise objective and independent judgment (Mallin 2019). INEDs effectively monitor management and help improve performance by ensuring compatible remuneration incentives for managers. INEDs are not incentivized to pursue short-term objectives for remuneration and so are more inclined to properly carry out their functions. INEDs enhance board independence and objectivity, transfer valuable knowledge to the company, and efficiently use its resources.

Succession and Evaluation

According to the UK Corporate Governance Code, an effective succession plan should be maintained for board and senior management (Financial Reporting Council 2018). “Appointments and succession plans should be based on merit and objective criteria and, within this context, should promote diversity of gender, social and ethnic backgrounds, cognitive and personal strengths” (Financial Reporting Council 2018). Furthermore, a “nomination committee is required to lead the process for appointments and ensure plans are in place for orderly succession to both the board and senior management positions. A majority of members of the committee should be independent non-executive directors. The chair of the board should not chair the committee when it is dealing with the appointment of their successor” (Financial Reporting Council 2018). The appointments of directors should be formal, rigorous, and transparent, and all directors should be subject to annual reelection. Directors should be appointed on an objective basis including merit and having sufficient time to effectively discharge their responsibilities.

The board and its committees should have a combination of skills, experience, and knowledge. Directors should receive a full, formal, and tailored induction on appointment and should regularly refresh their skills and knowledge by attending training programs. Furthermore, “consideration should be given to the length of service of the board as a whole and membership regularly refreshed. An annual evaluation of the board should also consider its composition, diversity

and how effectively members work together to achieve objectives.”

To ensure that directors have sufficient time to fulfil their role and responsibilities, several corporate governance codes have restricted the maximum number of concurrent directorships a person can hold (OECD 2004). The UK Corporate Governance Code states that the “chair should not remain in post beyond nine years from the date of their first appointment to the board. To facilitate effective succession planning and the development of a diverse board, this period can be extended for a limited time, particularly in those cases where the chair was an existing non-executive director on appointment and a clear explanation should be provided” (Financial Reporting Council 2018).

Audit, Risk, and Internal Control

Good corporate governance mandates the introduction of internal controls to ensure effective audit and risk prevention. The board of directors is also tasked with the “establishment of formal and transparent policies and procedures to ensure the independence and effectiveness of internal and external audit functions.” To ensure that auditors perform their functions, they should be individuals who are independent, competent, and ethical and possess personal integrity. The internal control system should achieve efficiency of operations, reliability of financial reporting, and compliance with applicable laws and regulations (Financial Reporting Council 2018; Mallin 2019).

The board should “establish procedures to manage risk, oversee the internal control framework, and determine the nature and extent of the principal risks the company is willing to take in order to achieve its long-term strategic objectives” (Financial Reporting Council 2018). Consequently, an audit committee should be established. The audit committee as a whole shall have competence relevant to the sector in which the company operates and should be responsible for reviewing the integrity of financial reports and overseeing the independence and objectivity of external auditors. In order to ensure that the audit committee fulfils its role and responsibilities effectively and independently, there should be a

minimum of three independent nonexecutive directors, or two in the case of smaller companies. At least one member must have recent and relevant financial experience. The chair of the board should not be a member (Financial Reporting Council 2018). The importance of the audit committee in ensuring effective corporate governance cannot be overemphasized. As Mallin (2019) puts it “the audit committee is arguably the most important of the board sub-committees.”

Remuneration

Directors should be adequately remunerated to ensure that they are motivated to pursue stakeholder interests. Inadequate remuneration fails to align manager and shareholder interests and impacts corporate governance practices and managerial conduct. While stronger remuneration packages would promote good corporate governance practices, caution must be exercised to ensure that management are not encouraged to pursue accounting malpractices for higher remuneration (Mallin 2019).

The UK Corporate Governance Code advocates for a remuneration committee to be established with a “minimum membership of three, or in the case of smaller companies, two tasked with deciding executive remuneration” (Financial Reporting Council 2018). Directors when authorizing remuneration outcomes are encouraged to “exercise independent judgement and discretion and take into account the company, individual performance as well as the wider circumstances” (UK Corporate Governance Code, 2018). Thus, the key is to ensure that executive remuneration aligns with the company purpose and values and is designed and clearly linked to support strategy and promote long-term sustainable success and that no director should be involved in deciding their own remuneration outcome.

Summary

The board of director is the primary internal corporate governance mechanism. The board is responsible for overseeing firm objectives and advising executive management. The board of directors is crucial to the corporate governance

agenda and helps resolve ethical issues by curtailing opportunistic behavior of executives. Consequently, efficient boards must provide strategic guidance which promotes accountability to stakeholders, and the presence of a competent and qualified management team.

A sound corporate governance strategy allows the board of directors to effectively execute their core functions, thereby reducing the reoccurrence of corporate collapses. Recent corporate collapses unearth significant failing on the part of the board of directors. There are examples of board of directors clearly ignoring good governance practices, personally enriching themselves, lacking requisite skills/qualifications to ensure full and effective oversight functions, lacking independence, possessing weak ethical standards, engaging in corrupt practices, and lacking commitment.

The strategic adoption of corporate governance practices and the creation of clearly defined boards that properly implement governance strategies, oversee risk management and remuneration packages, and manage succession planning should be encouraged in all firms. It is also imperative that there be clear distinction between management and control in order to safeguard board independence.

Definition

In the governance literature, the bonus identifies the variable component of incentive remuneration packages (Bryan et al. 2000; Jensen and Murphy 2004; Sanders 2001; Wu 2007) aiming to reward managers and executives (Izhakian and Yermack 2017; Kraus 2017).

In this regard, it is worth noting that the remuneration schemas encompass both the fixed wages and the short/long-term variable bonus pay (Conyon and Murphy 2000; Hoi and Robin 2004). Over the last decades, this latter component has experienced an increasing adoption even outside the Anglo-American companies where the widespread use of incentive remuneration packages started in the mid-1980s (Conyon and Peck 2001; Core et al. 2003). The tendency under scrutiny is especially pronounced for the bonus plans involving stock options that, since then, have been massively used in order to reward top managers and executives (Balsam 2002; Frydman and Saks 2010; Towers Perrin 2000, 2005). Indeed, while in the mid-1980s this kind of remuneration covered one-fifth of the average managerial compensation, in the 2000s its proportion has become the largest one, especially in the USA (Dunford et al. 2010; Hall and Murphy 2002; Murphy 1999).

However, the spread of incentive pays has not only questioned the remuneration gap between managers and rank-and-file employees (Hall and Liebman 1998) but it has also placed the factors that drive and affect the related use at the centre of the debate.

Stemming from these premises, the chapter illustrates the theoretical rationale of bonus pay and discusses the governance implications of such incentive remuneration component.

Theoretical Foundations and Governance Implications of Bonus Pay

From a theoretical standpoint, the rationale of granting the bonus pay lies on the divergence of interests between powerful reckless managers and dispersed heterogeneous owners described by the classic specification of the agency theory (i.e. agency problem type I) (Bebchuk et al. 2002; Berle and Means 1932; Jensen and Meckling 1976).

Building on this framework, some scholars posit that the incentive remuneration component under scrutiny is able to address the above-mentioned conflicts and motivate managers

toward the shareholder value maximization (Jensen and Murphy 2004; Towers Perrin 2000, 2005; Zattoni 2007; Zattoni and Minichilli 2009) as it limits their opportunistic behaviour (Ross 1973). Indeed, agency proponents argue that the presence of a direct link between managerial compensation and company performance (Jensen and Murphy 1990) provides managers (agents) with incentives to risk taking and value creation (Edmans and Gabaix 2011; Gormley et al. 2013; Harford and Li 2007; Hayes et al. 2012) by aligning their interests with those of shareholders (principal) (Bryan et al. 2000; Holmstrom and Costa 1986; Jensen and Murphy 2004; Wu 2007). This is especially true in companies characterized by widely dispersed ownership structures where the risks of misleading behaviour by managers and executives are sizable due to the high costs of their supervision (Bebchuk and Fried 2006; Shleifer and Vishny 1997).

The empirical research supports these conclusions and provides evidence on the alignment between the interests of shareholders and managers by highlighting that the incentive bonus pay is associated with higher pay-for-performance sensitivity (Kuang and Qin 2009; Jensen and Murphy 1990).

According to scholars, the bonus plan design is one of the main drivers of the alignment effect as literature suggests that its effectiveness encourages managers to maximize the shareholder value (Bebchuk et al. 2002; Bebchuk and Fried 2006; Johnson and Tian 2000; Kuang and Qin 2009; Zattoni 2007). This circumstance is particularly pronounced for the length of the incentive plan (Wheeler 2004) since the choice of long-term horizons hampers the managerial myopia and motivates managers to take value-maximizing decisions by discouraging their short-term opportunistic behaviour (Fudenberg et al. 1990; Hoi and Robin 2004; Jensen and Murphy 2004; Peng and Roell 2008). Shifting the attention to specific incentive pay schemas, such as the stock options, similar conclusions can also be drawn with regard to the identification of the related exercise price (Bettis et al. 2018). Indeed, the choice to link the striking price to the performance of comparable firms/competitors provides incentives to the firm

value maximization (Bebchuk et al. 2010; Bertrand and Mullainathan 2001; Johnson and Tian 2000; Sautner and Weber 2011) as managers are rewarded on the basis of their contribution to the value of company shares (Bebchuk et al. 2002; Kuang and Qin 2009).

Nevertheless, prompted by the wave of scandals in the late 1990s and the anecdotal evidence in the last decades, scholars have questioned the ability of the bonus remuneration to align the conflicting interests of managers and shareholders (Catuogno et al. 2016a, b; Tosi et al. 2003), even in companies with concentrated ownership structures (Melis et al. 2012; Zattoni 2007). In this regard, academics and practitioners emphasize that, in given circumstances, the incentive pay can be also symptomatic of an opportunistic behaviour and interpret the managerial grants as signal of extraction of private benefits (Bebchuk et al. 2002; Bebchuk and Fried 2006).

On the basis of these premises, scholars suggest that bonus plans prompt entrenched and opportunistic managers to expropriate the company wealth to the detriment of shareholders (Bebchuk et al. 2002; Bebchuk and Fried 2003, 2006; Core et al. 1999). In particular, powerful managers can take advantage of the board ineffectiveness (Andreas et al. 2012; Capezio et al. 2011; Chhaochharia and Grinstein 2009; Sun and Cahan 2009) and the collusive cooperation with the compensation committee to opportunistically set their own pay (Barontini and Bozzi 2009; Cao et al. 2011; Fracassi and Tate 2012; Goergen and Renneboog 2011; Gong 2011; Lin and Lin 2014). Therefore, in these circumstances, the bonus compensation tends to exacerbate the agency conflicts since managers receive pay in excess of the optimal amount for shareholders (Bebchuk et al. 2002; Bebchuk and Fried 2006).

Aside these arguments, it is worth noting that the use of the bonus pay can also be interpreted in the light of the related costs (Hall and Murphy 2002). Indeed, academics posit that the choice of the incentive remuneration under scrutiny relies on the costs and perceived risks (Zattoni and Minichilli 2009) that it entails since managers are especially concerned with their accounting

and tax implications (Catuogno et al. 2016a; Hall and Murphy 2003; Murphy 2002).

Overall, literature suggests that the attitude of bonus pay to address the agency conflicts or to foster the managerial entrenchment depends on the legal protection of investors provided by the regulation in force (Bender and Moir 2006; Coles et al. 2006; Perry and Zenner 2001; Rajgopal and Shevlin 2002) and on the type of ownership structure (Conyon 2014; Gomez-Mejia et al. 2007; Nyberg et al. 2010; Zattoni and Minichilli 2009). As for the former, studies emphasize that the stronger investor protection and the presence of disclosure compliance requirements of bonus pay are able to hamper the opportunistic behaviour of entrenched managers (Enriques and Volpin 2007; Liu et al. 2014; Nelson et al. 2010; O'Connor et al. 2006). With regard to the latter, the research is still inconclusive since it has not univocally interpreted the ability of incentive pay schemas to address the conflicts between managers and owners. In particular some studies highlight that, in widely held listed firms, these governance mechanisms effectively align the conflicting interests of manager and owners (Chalmers et al. 2006; Conyon 2014; Kuang and Qin 2009; Nyberg et al. 2010). Differently, other research draws opposite conclusions by suggesting that the strong managerial power due to this kind of ownership structures fosters the opportunistic use of incentive remuneration (Shleifer and Vishny 1997) and the extraction of private benefits to the detriment of shareholders (Core et al. 1999; Tosi et al. 2003).

The same inconclusiveness also characterizes the research efforts related to the blockholder-dominated companies (Barca and Becht 2001; Faccio and Lang 2002; Melis et al. 2012). Indeed, while some studies document that the incentive compensation is able to align the conflicting interests of owners and managers (Nagaoka 2005; Zattoni and Minichilli 2009), other research posits that the overlapping between directors/managers and owners allows blockholders to use remuneration to expropriate the firm wealth (Melis et al. 2012; Su et al. 2010). This last circumstance is especially pronounced for companies ruled by control enhancing mechanisms (Cao et al. 2011; Cuomo et al. 2012; Institutional Shareholder

Services 2007; Saggese 2013, 2018; Saggese et al. 2016) as well as when the concentrated ownership is combined with the family control (Barontini and Bozzi 2009). Indeed, literature suggests that the deviation from the proportionality principle due to control enhancing devices (Adams and Ferreira 2008; Burkart and Lee 2008; Grossman and Hart 1988) provides majority shareholders with incentives to extract private benefits of control through the incentive compensation (Barontini and Bozzi 2009; Chourou 2010; Haid and Yurtoglu 2006; Masulis et al. 2009; Tinaikar 2014). Similar conclusions are drawn with regard to the firms controlled by a family owner. Indeed, research documents that the incentive pay can be used by opportunistic family managers to extract rents to the detriment of non-family shareholders (Berrone et al. 2010; Gomez-Mejia et al. 2007; Kellermanns et al. 2012; Morck and Yeung 2003; Stockmans et al. 2010; Zattoni and Minichilli 2009).

Notwithstanding the scholarly efforts to identify the implications of incentive bonus pay, there are still open issues on how the governance characteristics (i.e. governance mechanisms and governance roles) and the exogenous features of financial markets interact, thus affecting the use of this tool. Thereby, future research efforts should be devoted to assess the interplay of both the internal and the external forces responsible to drive the adoption of incentive bonus pay.

Summary

The chapter illustrates the theoretical underpinnings of the bonus pay adoption and provides an overview on the governance implications of such incentive remuneration element.

Synonyms

Additional compensation; Benefits; Extra compensation; Fringe benefits; Incentive system;

Performance-based compensation; Premium; Special compensation; Variable compensation; Variable income; Variable payment

Definition

Bonuses are variables payments assigned to employees upon reaching some predefined goals. The bonus pays are usually tied to company outcomes (e.g., profits, share price, sales, customer satisfaction) as well as linked to specific employee's area of responsibility so as to allow the identification of the individual efforts and results. Bonuses pays could be tied to the achievement of short-term, intermediate-term, and long-term goals.

Introduction

Over the last decades, firms have radically changed their pay practices, especially at managerial level, where employees are given much greater benefits for the services they provide, and a much larger portion of their pay is based on the firm performance or deemed "at risk" (Magnan and Martin 2019).

Indeed, it is worth noting that the employee compensation can be made up of various components and, besides the fixed cash salary, there are a lot of additional and nonmonetary benefits (e.g., tax consultant services, medical check-ups, company car, furniture for company housing) as well as perquisites (e.g., club memberships). Nevertheless, in recent years the biggest part of the remuneration consists of the performance-based rewards, as additional monetary benefits which mostly consist of direct (cash) bonuses or equity-based bonuses (Luthans and Stajkovic 1999). Anecdotal evidence confirms this trend. Indeed, looking at top managerial compensation, there is the case of the CEO of Chrysler, Lee Iacocca, who gained a nominal cash salary of \$1 but earned \$35 million in stock options gains (Catuogno et al. 2016a, b). Additionally, according to a study provided by the Hay Group in 2009 on the CEO compensation in US, while the CEO base salaries

have significantly decreased from 2008 to 2009, in the same time frame the annual incentive pay grew of 3.4%. Indeed, the number of organizations that largely employ incentive plans in order to remunerate and reward the performance of outperforming employees has significantly increased (Falola et al. 2014). The main aim is to design the incentive packages to get the maximum performance from their employees as well as to retain the most productive ones among them (Arnold 2013).

Scholars suggest that an adequate incentive-based compensation scheme represents a crucial instrument through which organizations can motivate and increase their workers' performance. Indeed, studies belonging to different field (e.g., management literature, accounting literature) have documented that the use of incentive plan in employees' compensation influences workers performance by inducing a higher level of their efforts (Gomez-Mejia et al. 1987; Tosi and Gomez-Mejia 1994; Chow 1983; Waller and Chow 1985; Chow et al. 1988). Also, there are many studies that have empirically examined the implications of incentives plans for firm outcomes (Al-Nsour 2012; Arnolds and Venter 2007; Banker et al. 1996). Overall, these studies document that measuring and rewarding the performance of employees encourage and sustain employee contributions to the success of the organization for a number of reasons (Milkovich et al. 2010).

First of all, according to the expectancy theory, the employees' motivation and therefore their productivity are enhanced as their behaviors are highly instrumental in achieving the desired outcomes. Indeed, linking the employees' compensation to the outcomes of their behaviors, enhances the expectation of receiving rewards tied to a specific outcome as well as the motivation of employees to engage in the behaviors that allow to achieve the desired outcomes (Gerhart and Milkovich 1990; De Kok et al. 2006). In this regard, scholars suggest that performance-based remuneration system in which efforts and rewards are characterized by specific individual goals, represent the best tool to increase the employee's motivation (Fay and Thompson 2001).

From a different standpoint, research enlightens that incentive compensations are able to align the interests of employee and owners, especially with regard to employees at managerial level (Kruse et al. 2010). In this regard, according to the agency theory, the incentive performance-based bonuses are able to address the conflicts of interest between the owner (i.e., principal) and the employee (i.e., agent) (Jensen and Meckling 1976). Indeed, the theory stems from the problem of the employment which involves that the owner delegates his work to an agent who performs his job in return for some remuneration. However, as a self-interested rationalist, the agent will try to avoid performing the contracted obligations by taking advantage of the principal inability to control all aspects of his behaviors. In this regard, the principal could invest in monitoring behavior or, in alternative, in using incentive compensation systems that rewards the agent based on firm outcomes, so as to resolve the above-mentioned issue (Gerhart and Milkovich 1990). Indeed, by making workers' remuneration contingent on organizational-level outcomes, such as shareholder profit or value creation (Ross 1973), employees are better able to behave as owners and are also more likely to take risk (Coles et al. 2006; Edmans and Gabaix 2011; Gormley et al. 2013; Hayes et al. 2012).

Additional benefits of using remuneration packages that include variables payments compensation are linked to the firm's ability to draw talented employees compared with untalented ones (Hancock et al. 2013; Long et al. 2002). Indeed, as brilliant employees are more confident to increase company value, they are more committed to do so (Chrisman et al. 2017; Long 2000), with obviously positive implications in terms of the improvement of the level of firm performance.

Finally, the positive implications of incentive compensations also occur in terms of group coordination. This is especially true when the employees reward is based on the product of group-based assessments instead of individual ones, as it increases the degree of cooperation among employees within the firm (Blinder 2011; Nyberg et al. 2016). Indeed, the performance group-based compensation encourages employees to monitor each other by hampering the level of the

team effort and productivity and by reducing the free-riding co-workers effect (Kruse et al. 2012).

Stock-Based Incentive Compensation Plans

Among several key components of bonuses, stock-based incentive compensation plans are recognized as the most effective way to relate pay to performance (Zattoni 2007). This is especially true for employee at managerial level as they usually represent the main part of the overall managerial compensation. Indeed, Damodaran (2015) documents that on average, in 2013, 70% of the CEO compensation package in US is equity-based, while cash compensation (salary and cash bonuses) is lower than 25%.

From a technical point of view, literature has classified stock-based incentive compensation plans into two main groups: (i) non stock option plans and (ii) stock option plans. While the former link employees' remuneration to the value of firms' shares, the latter provide employees with the possibility to buy or subscribe company shares (Bernhardt 1999; Zattoni and Minichilli 2009).

Focusing the attention on non-option stock plans, these tools can be classified into two categories (Zattoni 2007). The former has a higher incentive goal and includes those plans granting a reward to employees for achieving certain targets. This is the case of phantom stocks that give a bonus (in cash or stock) if the firm share price has increased, or additionally of stock appreciation rights that assign to employees a cash premium award equal to the difference between the market share price and a predefined strike price. The second group of non-option stock plans is composed by share ownership plans, where granting share is part of a more general employee shareholding scheme. This group includes instruments that assign stocks to workers, free or under convenient conditions (i.e., stock grants) or that they have to sell back to the company whenever some targets are not achieved (i.e., restricted stock plans) (Zattoni 2007; Catuogno 2013).

Shifting the focus on the stock option plans, this kind of incentive plans give workers the right to

buy or subscribe stocks, after (i.e., vesting period) and within (i.e., exercise period) a certain time period, at a predefined price (i.e., strike price), and sometimes conditionally to the achievement of some firm performance targets (Zattoni 2007). These bonuses represent a motivational contract tool as employees are encouraged to increase the value of company shares because if it overcomes the strike price, they can buy and later sell firm stocks, gaining the difference between the strike and selling prices (Jensen and Murphy 1990). Irrespective of the aim of stock option plans, it is worth noting that these tools can differ according several variables such as the qualification of the involved employees (i.e., broad-based stock option vs executive stock option plans), the method of presetting the strike prices (i.e., fixed stock option plans, variable stock option plans, or indexed stock option plans), or the presence of a link with a firm performance variable (i.e., market performance plans vs enterprise performance plans).

Despite stock option plans and non-stock option plans present some basic similarities as they both link managerial remuneration to the value of the firm's equity, the abovementioned peculiarities involve that they overall differ in terms of risk profile, motivational effect, financial resource required and link with the achievement of firm targets (Zattoni 2007).

Stock Option Plans

Literature has interpreted the use of stock option plans as a compensation tool in the light of the agency problem between managers and shareholders in Anglosaxon public companies (Berle and Means 1932; Catuogno et al. 2016a). Indeed, according the optimal contracting theory, by linking executives compensation to shareholder value, stock options represent a governance tool able to diminish managerial opportunism and to align the interests of managers (agents) and owners (principal) (Ross 1973; Zattoni 2007; Holmstrom and Costa 1986; Jensen and Meckling 1976). Following the alignment rationale, stock options represent a tool able to increase the company performance and maximize the shareholder

value (Jensen and Meckling 1976). Indeed, by providing managers with a proprietary interest in the company, they will achieve both their own and shareholder goals (Murphy 1999).

However, some recent financial scandals in European and US companies have suggested that stock option plans can often fail to solve the conflicting interests in dispersed ownership structures (Terviö 2008; Tosi et al. 2003), and they are also sometimes employed in the presence of blockholders (Catuogno et al. 2016a; Melis et al. 2012; Zattoni 2007).

In this regard, proponents of the rent extraction view (Bebchuk et al. 2002) have suggested that that stock options may represent an additional tool for powerful opportunistic managers to increase their wages and “camouflage” inefficient wealth transfers from shareholders to them (Bebchuk and Fried 2003, 2006; Hall and Murphy 2002). Still building on the agency theory, this framework suggests that powerful managers receive a pay in excess (i.e., a rent) of the optimal level as they are able to condition their own compensation arrangements (Bebchuk et al. 2010; Bebchuk and Fried 2006). In this regard, literature suggests that badly designed stock option plans may usually represent a signal of the agency conflict, instead of a governance mechanism able to solve it (Bebchuk et al. 2002; Bebchuk and Fried 2006; Terviö 2008; Barontini and Bozzi 2009).

Building on this, it is worth noting that the aim of stock option can be interpreted as a double-edge sword. However, scholars have suggested that the design of stock options plan is able to ensure the alignment aim of stock option (Catuogno et al. 2016a). Indeed, governance literature advocates that the strike price, the vesting period, the lockup period, the vesting conditions, and the repricing play a crucial role to define an effective stock option plan (Catuogno et al. 2016b; Bebchuk et al. 2010; Kuang and Qin 2009). More specifically, both research and practice emphasize that the abovementioned elements should be effectively designed in order to achieve a long-term remuneration perspective that motivates managers to take value-maximizing decisions (Catuogno et al. 2016b).

First of all, with regard to the strike price, research documents that setting the exercise

price equal or higher than the current share market price at the assignment date increases the managerial incentive to pursue shareholder wealth and to boost the shareholders' returns (Bebchuk and Fried 2006). Therefore, an at-the-money/out-of-the-money strike price pushes managers to increase the market stock price so as to benefit from the emerging capital gain (Catuogno et al. 2016b; Zattoni 2007). Opposite conclusions are drawn if at the assignment day the strike price is already equal to the current market value of the underlining share, as the option is already in the money, and managers are not incentivized to achieve the shareholder value maximization (Bebchuk and Fried 2006; Zattoni 2007; Balsam and Miharjo 2007).

Shifting the focus on the vesting period, studies document that the an effective design of stock option plans requires a long vesting period in order to avoid the "managerial myopia" (Catuogno et al. 2016b; Peng and Roell 2008), as it involves a higher share prices at the exercise date (Liljebloom et al. 2011; Fudenberg et al. 1990). Similar conclusions can be drawn with regard to the lockup period, as its presence pushes managers toward medium-/long-term firms goals. Indeed, executives are dissuaded to adopt a short-term opportunistic behavior due to their inability to shortly exercise the options and sell the shares (Melis et al. 2012; Zattoni and Minichilli 2009). Thus, studies in this tradition advocate that both the presence and the length of vesting, and lockup periods are crucial for the achievement of the rent extraction or the alignment purposes (Wheeler 2004).

Literature suggests that an additional element able to influence the effective design of stock option plan is the existence of an indexed strike price as a vesting condition (Catuogno et al. 2016a; Bebchuk et al. 2002; Sautner and Weber 2016). Indexed exercise prices ensure that managers are rewarded only if they really provide a contribution to the rise of company value. The underlying assumption is that the stock price changes could be not completely linked to the managerial performance, but influenced by market trends and expectations (Kuang and Qin 2009; Bertrand

and Mullainathan 2001; Johnson and Tian 2000). However, indexed strike prices ensures that the options can be exercised when company share prices exceeds their market peers share prices (Hall and Liebman 1998), avoiding that executives are rewarded even if they have not conditioned the rise of company value (Bebchuk et al. 2002).

Finally, it is worth noting that an efficient design of stock option plans should not allow to re-set the exercise price if the original one is higher than the current value of the stocks (Chen 2004). Indeed, this could allow executives to gain boundless remunerations if the market price increase, or to protect themselves from the losses in the opposite case (Catuogno et al. 2016b; Catuogno 2013). Therefore, scholars suggest that the repricing is able to challenge the alignment aim of stock options leading to the rent extraction purpose (Chance et al. 2000; Chidambaran and Prabhala 2003).

Summary

This entry illustrates the main objective and characteristics of incentive compensation plan, with particular reference to the equity-based ones.

Definition

Brands are a widely discussed topic in the academic literature – yet depending on the sources and the conceptual frameworks, the term branding has several different definitions with various perspectives which constitute brand meaning. One of the most cited definitions comes from the American Marketing Association, which defines a brand as: “A brand is a name, term, design, symbol or any other feature that identifies one seller’s good or service as distinct from those of other sellers” (AMA 2014). Considering this definition, brand management includes all the strategies and processes that are aimed at creating, maintaining, and improving brand equity and performance over time.

Introduction

Customers, on average, are exposed to approximately 5 000 brands per day. It is therefore clearly impossible to memorize them all. Therefore, a good branding and brand management strategy will seek a precise positioning for selected customers, easing their decision-making, reducing the risk of a wrong choice, and creating (emotional) value. By doing so, the brand will stand out from the mass.

Brands thus represent valuable assets for companies and can significantly contribute to their financial success. Therefore, they must be managed strategically, which again requires a consistent nurture and maintenance of the brand. Consequently, brands can generate competitive advantages through outstanding product performances as well as independently of the product only with the help of favorable image associations (Keller 2013, pp. 31–32). “A brand is thus as an amalgam of interpretations” (De Chernatony 2010, p. 73).

Although the impact and the functions of brands are indisputable nowadays, there is no consistent and approved definition of brands yet. This can be attributed to numerous changing factors over time, such as environmental conditions and the relationship between manufacturer and

retailers, which have affected the brand understanding and brand management consequently.

Historic Development of Conceptual Branding Definitions

According to Bruhn (2004, p. 9) and Baumgarth (2014, p. 3), the historic definition approaches of brands can be classified into the following systematization:

- Legal approach
- Characteristic-based approach
- Supply-oriented approach
- Demand-driven approach
- Identity-based approach

The idea of branding is no contemporary invention, a few centuries ago livestock farmers already distinguished their products from competitors by means of burned-in signs. For this reason, “[...] the word brand is derived from the Old Norse word *brandr*, which means to burn [...]” (Keller et al. 2008, p. 2).

Until the mid-1960s, brands were defined as bundles of characteristics, and they were distinguished from unmarked products.

Regarding selected characteristics, this approach must be viewed critically, e.g., finished products exclude persons, cities, and even countries as brands although they represent brands in fact. The characteristic-based approach thus offers many indications on how to make a successful brand, but it fails to consider the demand perspective and other forms of brands besides finished products (Schwertfeger 2017, p. 3).

In the following supply-oriented approach, the characteristic-based brand understanding was replaced by a brand understanding based on the marketing efforts of the suppliers. Here, brands are defined as a set of sales-related marketing instruments. However, this definition approach lacks general validity, as it cannot be applied to all common sales approaches (Baumgarth 2014, p. 4).

Due to an increasing competitive orientation on the market, a demand-driven approach was

developed in the 1980s, which dealt with the external impact of a brand on the consumer (Bruhn 2004, p. 9). All products and services were regarded as branded products, which consumers identified as such. Although the operationalization of the brand impact on the consumer has led to disagreement among scholars, brands must at least provoke a high brand recall, a distinctive image, and a preference to attract consumers’ attention (Baumgarth 2014, p. 5).

In the 1990s, the demand-driven approach was supplemented by the view of the company, which led to an identity-based approach (Aaker 1996; Meffert and Burmann 1996). In this approach, the brand is treated from a sociopsychological perspective, which is based on the interaction between the company perspective (brand identity) as well as the consumer perspective (brand image) (Schwertfeger 2017, p. 3). The brand identity reflects an internal image of the own brand, which is actively shaped by all brand relevant characteristics. It forms the basis for a sustainable differentiation from other brands. Through the brand promise (positioning) and the linked brand behavior, the company aims at conveying its internal image to the consumer from the inside-out (Meffert et al. 2015).

By contrast, the brand image is shaped by the consumer and can therefore only be influenced indirectly by the company. It results from the perception and decoding of all signals emitted by the company, for which it makes use of the consumer’s brand expectations and brand experiences at all available brand touchpoints. Consequently, the brand image is built over a certain period and with a time delay, compared to the brand identity (Meffert et al. 2015).

Only if a company manages its brand individually, consistently, and continuously at all touchpoints with its consumers, brand authenticity can be achieved, which improves brand trust and thus ensures the success of a brand.

Strategic Brand Management

Traditional strategic brand management encompasses firms’ efforts around the customers’

engagement with brands by designing and implementing appropriate marketing programs in order to create favorable outcomes including high brand loyalty (Keller 2013, p. 58). This loyalty is often viewed as the “holy grail” of marketing and may be achieved – as the flip side of brand equity – through savvy relationship management (Shugan 2005, p. 185). Building brand equity requires programs which properly position the brand in the customers’ minds and foster strong customer-brand relationships. This kind of marketing approach may provide organizations with benefits: Customer profit rates tend to grow over the life of transactions between brands and retained customers whose retention costs five times less than new customers’ acquisition (Keller 2013, p. 183).

Customer-Based Brand Equity

The CBBE concept approaches brand equity from the customer’s point of view and rotates around the idea that brand knowledge has a positive and differentiating effect on consumers’ responses to brand management efforts. Accordingly, a brand has a positive (negative) CBBE when customers react more (less) favorably to the product and its marketing when the brand is clearly identified than when it is unnamed. According to the concept, brand knowledge is regarded as the key to building brand equity since it drives the differential effect mentioned above. This knowledge has been defined in terms of its two components brand awareness and brand image which also represent the sources of brand equity: The former reflects the consumer’s ability to identify the brand and comprises brand recognition and brand recall, meaning the brand’s retrieval in consumers’ minds. Brand image, on the other hand, refers to brand associations held in consumers’ memories that may be either brand attitudes, attributes, or benefits (Keller 2013, pp. 70–73).

According to the so-called brand resonance model, building a strong brand embraces a sequence of multiple steps which build on each other and are carried out successively. Thus, the order of these steps is often associated with a branding ladder including four stages of brand

development. However, this brand-building process is complicated and difficult; thus it is often structured and illustrated in six brand-building blocks assembled in a pyramid in order to provide clarity. Creating significant brand equity requires reaching the top of the pyramid (Roper and Fill 2012, p. 164; Keller 2013, p. 107).

Brand Identity

Brand identity forms the foundation of the model and requires creating high brand salience in terms of the brand’s retrieval in consumers’ minds. However, deep and broad brand awareness is usually not sufficient, and the next level, brand meaning, comes into play (Roper and Fill 2012, p. 164; Keller 2013, pp. 107–111).

Brand Meaning

Building brand meaning includes establishing a brand image and may be differentiated in terms of more rational performance-based considerations and more emotional, abstract imagery-based perspectives. Brand performance, on the one hand, measures the extent to which the brand’s product and service attributes satisfy the customers’ needs and wants (Keller 2013, pp. 111–113). Brand imagery, on the other hand, deals with the more intangible aspects of the brand and may be formed directly by own experiences or indirectly by advertising or word of mouth. Four sets of associations linked to a brand may be identified which involve user profiles, purchase and usage situations, personality and values, as well as history, heritage, and experiences: Whereas the first two categories relate to types of brand users and situations in which the brand could be bought or used, the other two sets cover the brand’s personality traits and associations with the brand’s heritage. Brand performance’s and imagery’s interplay creates unique and favorable brand associations which are key in building CBBE and help to reach the level of brand response (Keller 2013, pp. 83–88).

Brand Response

This stage relates to the customers’ response to the brand and its marketing and may be distinguished in terms of brand judgments and brand feelings.

The former include customers' personal evaluations and opinions about the brand's quality, credibility, consideration, and superiority (Keller 2013, p. 117). Favorable perceptions of quality and credibility are crucial however not sufficient if consumers do not incorporate the brand in their "[...] set of possible options of brands they might buy or use" and do not consider the brand unique and better than competitive brands (Keller 2013, p. 118). Brand feelings, on the other hand, refer to consumers' emotional reactions and responses to a brand, including, for instance, excitement or social approval (Keller 2013, pp. 118–120). Customers' positive reactions towards the brand may be a consequence of brand response; however, reaching the final level of the pyramid – a relationship between the customer and the brand – requires creating high brand resonance (Keller 2013, p. 120).

Brand Resonance

This relationship's nature is manifested in loyal and highly engaged customers who feel a personal attachment with the brand and are willing to invest resources in the brand beyond those spent during the purchase or consumption. Eventually, a sense of affiliation with other brand users contributes to the creation of brand resonance. Indeed, by reaching this stage of the pyramid, a brand equity and thus high customer loyalty have been established. The abovementioned sense of bonding with other people associated with the brand may be referred to as the brand community which will be examined in greater depth in the subsequent section.

In today's world, there is a great need for adequate branding due to increasing globalization. Changing market conditions, increasing competition, product distinction, behavioral habits, and customer credibility can be considered major challenges. The commoditization of products, giving consumers a wide range of alternatives to a certain product or need, makes it impossible to choose one product or service over another without looking at brand names. A lot of companies use "fast communication" rather than appropriate branding strategies. The marketing tools and instruments are exploited before an

actual branding process takes place. This can be explained by the similar general principles and frameworks of both: branding and marketing (Chernev 2017, p. 3). The strategic side of branding is not fully understood and performed, and therefore marketing and branding are often considered the same concepts. Thus, a brand's uniqueness cannot be recognized as marketing focuses more on several product features instead of a distinctive value proposition. Gaining a clear competitive advantage gets more difficult to achieve but, at the same time, is necessary to position a company successfully in the market and to create brand awareness in a globalizing world (Gronlund 2013).

In general, there is no consensus in the literature for the meaning of the term brand. It can however be stated that the underlying idea of a brand is that a consumer is able to perceive several attributes in the goods or services of a provider in such a way that the consumer identifies the supplier directly. Brands have a wide range of characteristics that, in today's economic and social environment, have to be involved to support the marketing processes directly and indirectly. Therefore, before executing any marketing measures, a brand must begin with positioning itself in the market. The brand identity acts as the foundation of the brand management and represents the self-image of a brand. It is the basis and formulates objectives for the positioning, which gives the brand its own and unmistakable profile. A clear competitive advantage must be visible while addressing the needs of the target audience to further influence the brand image, the external perception in the eyes of the stakeholders (Gronlund 2013, p. 2). Ideally, the potential customer immediately recognizes a brand by its color, design, and logo (brand identity) and consequently creates a brand image. If a brand manages to reflect a positive brand image successfully, it offers benefits from both a consumer and a supplier perspective. In accordance with established literature on this topic, there are three broadly categorized benefit aspects for a customer: Identification and orientation function (information efficiency), trust (risk reduction), and identification and prestige (image benefits).

These customer advantages also fulfill several benefits for the supplier.

Numerous opportunities for the brand management of a company are created through customer benefits. A brand gives the opportunity for an entrepreneur to be profiled and to increase the economic brand value. According to Chernev (2017), creating market value must be the overall objective of a brand. In this context, the brand serves to create preferences and differentiation from the competition. If a company manages to create consumer satisfaction with its performance, it eventually increases customer loyalty. From a business perspective, these aspects are also of great importance in connection with sales development and planning. It offers the opportunity to serve market segments with different target group-specific brands in the best possible way. A company can therefore position itself in different segments in an optimal way, each pursuing a specific brand policy. In this case, one speaks of segment-specific market cultivation. In addition, the so-called line extensions enable the establishment of new products of the same brand in product categories that are already served. Successful brands also create a scope for pricing policy. The more successful a company's brand management, the greater its scope to adapt prices. This goes hand in hand with an increase in the value of the company. In this context, experts often outline that brands also have a life cycle. A life cycle is known originally from the goods industry, describing its development through the time on the market. To extend the life cycle of a brand, it must be ensured that the brand is sustained in the long-term by the support of the above-illustrated functions (Kapferer 2012). Thus, brand visibility can be highlighted through line extensions which are consequently saturating short-term demands. Distribution extensions make brands more available in the long-term and renewed advertising or communication can be used additionally. Price reductions and new innovations offer new competitive advantages, and, in the same way, the value creation of a brand can be strengthened. Lastly, repositioning can be used to extend and rearrange the brand's value. Consequently, a brand's life cycle can be sustained if the functions

are optimally supported by respective measures (Kapferer 2012).

These are the strategic brand management tools by which the brand is built and sustained in the long-term. Furthermore, it is highly recommended that branding should be regarded about how to strategically develop a meaningful and loyal relationship to the customers and about creating market value and not about the amount of effort a company puts into marketing activities (Gronlund 2013, p. 3). Nevertheless, marketing activities are the asset in supporting efficient brand management. These measures must be consistent with a brand's positioning strategy.

Development of Brand Management

Since decades, companies and researchers try to develop theories and ways on how to develop a strong and appealing brand because brands are often invoked as the most valuable assets of a company. A dominant brand correlates positively with a higher market share (Smith and Basu 2002, p. 21), and strong brands are more resilient to a product harm crisis (Dawar and Pillutla 2000, p. 224). Further, brand loyalty leads users to be more likely to counter-argue negative information about the brand (Ahluwalia et al. 2000, p. 10). Branding creates trust and emotional attachment and therefore influences the buying. Thus, thousands of publications deal with the topic of brand management and, in general, how companies can create a strong and appealing brand.

In intensive research of 300+ journal articles conducted by Heding et al. (2009), brand management theories from 1985 to 2008 were analyzed. As a result, the authors found seven different approaches to brand management and thus, how brand managers see the brand-consumer interaction. "These [...] approaches complement rather than substitute each other [...]". Further, the authors "[...] stress that the birth of one approach does not imply the end of the 'previous' one[s]" (Heding et al. 2009, p. 21). The seven different approaches to brand management reflect the thinking of the research period. However, many parallels to today can be drawn and valuable information

deducted. In the following, the seven approaches are structured in chronological order of their appearance.

The economic approach is based on neoclassical microeconomic theories and ideas from transactional marketing. Hence, brand management focuses on understanding marketing mix factors which influence consumption decisions, because “the exchange between brand and consumer consists of isolated transactions rather than an ongoing relationship” (Heding et al. 2009, p. 34). By focusing only on the marketing mix, brand managers assume that consumption choices are made due to rational reasons with consumers searching for brands delivering a high utility compared to their price. Thus, consumers are seen as aiming to maximize a product’s utility. As a result, the economic approach sees the consumer as a passive recipient of brand communication. The linear brand communication focuses on reaching the consumer at the right time and ensures that consumers are aware of the brand utility (Heding et al. 2009, pp. 34–45).

The identity approach assumes that brand value creation correlates positively with a strong brand identity. This view marks a shift from a product-level focus to a corporate-level branding focus because brand managers focus on creating a coherent identity.

Hence, the effect of organizational behavior changes on brand identity, brand image, and brand reputation is a concern of brand managers. Furthermore, the consumer is not seen as a passive recipient anymore since brand identity cannot be communicated only in a linear way “but is the result of negotiation between internal and external shareholders” (Heding et al. 2009, p. 55). As an implication, brand managers need to ensure that all stakeholders experience a strong coherent brand identity across all touchpoints with the company (Heding et al. 2009, pp. 47–79). The brand is linked to consumer associations.

The consumer-based approach assumes that a brand is a cognitive construct in the consumer’s mind. Brand managers can influence brand perception inside the mind of the consumer by listening to consumers and choosing the right brand elements and the right communication. In this

approach, brand managers “[are] seen in charge of communications as an assumption of linear communication applies to the cognitive consumer perspective” (Heding et al. 2009, p. 108). Further, brand managers should position the brand with consistency as memory is based on permanent and durable recognition (Heding et al. 2009, pp. 83–113).

The personality approach assumes that consumers project human personality and human attributes to brands. In this approach, brand personality plays a significant role in determining the brand strength as consumers search for a brand-consumer personality fit (Heding et al. 2009, pp. 116–149). Thus, brand managers need to focus on building an “attractive and relevant brand personality” (Heding et al. 2009, p. 147).

The relational approach emphasizes a viable brand-consumer relationship leading to a significant paradigm shift. Consumers are not seen as passive recipients but rather as active partners. Brand loyalty is often closely linked with the perception of the quality of a relationship and is an essential foundation of the relational approach. Furthermore, the “inner reality” of consumers is taken into consideration when the phenomenological perspective distinguishes a holistic view with several indirect factors influencing consumer choice. Brand managers need to leave full control of the brands since brand-consumer interaction is a dyadic and dynamic process with a risk of information overload while trying to integrate consumer information into brand communication. As a result, consumers are not only seen as an information source but rather as a respective partner (Heding et al. 2009, pp. 151–178).

The community approach assumes that consumers should interact with one another as brand managers are outnumbered and the management of a brand becomes increasingly difficult. This approach observes that brand loyalty and a deeper inner consumer-driven brand perception are significant advantages of the interactive involvement of consumer groups. For managerial implications, this approach sees brand managers as discrete observers and facilitators, which do not try to convince the individuals in the community to purchase the newest products. Instead, brands

need to aim for a high involvement of its community members and encourage the sharing of consumption experiences (Heding et al. 2009, pp. 181–204).

The cultural approach assumes that brands “act as a cultural artifact” (Heding et al. 2009, p. 112). With this approach, the macro-perspective of brands becomes significant and focuses on the cultural influence of brands. Hence, brands can act as iconic brands or establish an anti-brand movement with brands being more successful when they integrate themselves into the social culture. Thus, brand managers need to develop cultural understanding, providing brands with cultural meaning and monitor cultural changes in brand perception (Heding et al. 2009, pp. 207–239).

Considering these approaches, a positivistic and a constructive paradigm of brand management approaches is identified. The positivistic paradigm emphasizes that brands are “owned” by brand managers, who control the communication to a passive consumer. In contrast to that, the constructive paradigm was developed later and views a brand and its value created in the interaction between brand managers and an active consumer. These brand management approaches show that brand management is constantly changing. This is particularly relevant today, as technological progress is accelerating, and social views are strongly influenced by social media and the Internet.

Identity-Based Brand Positioning

Considering the development of brand management approaches, the latest brand management approaches focus on the importance of social interaction and being part of a broader cultural artifact. Consequently, brand positioning and brand perception become decisive factors for successful brands. Burmann et al. (2018) express this in similar terms: Successful brand management cannot be based exclusively on the requirements of the market and the view of the demanders. It is only the internal view of the brand, its identity, that allows differentiating the own brand from the competition in the long run. The combination of the outside-in with the inside-out perspective

represents the core idea of identity-based brand management (Burmann et al. 2018).

The identity-based brand positioning comprises four steps that make up the management process of brand positioning. These four steps are the development of the brand positioning towards a target identity, the compression of six identity components into symbolic-functional customer benefits, the translation into a brand-benefit promise, and finally the communication of the brand message to the target group (Burmann et al. 2018). The brand-benefit promise must be conveyed in a way that is suitable for the target group. This is done using the entire marketing mix as well as the appearance and behavior of the employees at all the brand touchpoints, which the consumer has with the brand. To a greater extent, the brand identity is composed of these six identity components (Burmann et al. 2018, p. 103):

- Services (what do we offer?)
- Competencies (what can we do?)
- Origin (where do we come from?)
- Vision (what do we want to achieve?)
- Personality (how do we communicate?)
- Values (what do we believe in?)

These identity components play an essential role in providing customer benefits, which are categorized into functional and symbolic benefits. Depending on the brand identity, the functional benefits (utilitarian, economic) and the symbolic benefits (aesthetic, hedonistic, social) differ (Burmann et al. 2018). The brand image and the consideration of customer need through feedback are impacted by ideals and previous experiences and mark the outside-in perspective of this theory. This is combined with the inside-out perspective, which analyzes the companies own resources and competence to meet the needs of the customer (Burmann et al. 2018).

To ensure the sustainable success of brand positioning, it is essential that the individual underlying factors of the four-step management process are optimally addressed. A lack of credibility of the brand value proposition has a high adverse effect on the success of the positioning. The brand value proposition should also be

understandable for the target group and relevant and superior to competing brands. In practice, there are often significant discrepancies between the target positioning and the actual positioning, and consequently, the failure of the target positioning and the actual positioning. Summarized, the result of this four-step management process is a precise position of the brand in the minds of the consumers and, thus, a particular brand image (Burmman et al. 2018).

Definition

Bribe Payers Index (BPI) was launched in 1999 by *Transparency International*, a global civil society not-for-profit organization that works with governments, businesses, and citizens to alleviate corruption around the world. The organization has an international secretariat in Berlin, Germany, and charters in more than 90 countries.

BPI appraises the supply side of corruption. It looks at the probability of companies from the world's developed nations to bribe overseas. Governments are often complicit in exporting corruption by allowing firms located in their countries to use bribes to win businesses abroad. Between 1999 and 2011, the BPI ranked the globe's wealthiest nations by the propensity of their companies to bribe overseas. The reports were based on surveys of thousands of senior business officials from both developing and developed countries and also looked at the worst offenders by industrial sectors. The reports are available for 1999, 2002, 2006, 2008, and 2011. The projects were partially underwritten by the *John D. and Catherine T. MacArthur Foundation*.

Key Issues

The inaugural *BPI* report of 1999 was based on a study commissioned by *Transparency International* and conducted by *Gallup International Association (GIA)* with private sector executives in 14 developing market economies accounting for over 60 percent of all imports. The survey

was conducted between April and July 1999 in Argentina, Brazil, Columbia, Hungary, India, Indonesia, Morocco, Nigeria, Philippines, Poland, Russia, South Africa, South Korea, and Thailand. Professionally trained interviewers conducted 779 interviews – approximately 55 in each country. About one-third (230) of the informants were senior executives, resident in emerging market countries, and employed by foreign multinationals, while another third (236) represented major national companies. The remaining respondents were charter accountants (84), from binational chambers of commerce (78), domestic and foreign commercial banks (78), and commercial law firms (75).

Overall, the report provides a troubling picture of bribe-paying practices in the leading exporting countries. The key factors influencing such practices appeared to be remarkably similar to each other. The primary reason attributed to an increase in bribe-taking was most senior officials receiving low salaries (66% of respondents). Immunity of public officials (63%), secrecy in government (57%), worsening public procurement practices (51%), the privatization process (37%), increase in foreign investment and trade (30%), restrictions on the media (24%), and financial liberalization (19%) were found to be the additional reasons for increasing bribe-taking.

The countries are rated on a 0–10-point scale, where 10 corresponds to the interpretation that firms from a country never engage in bribery when conducting business abroad. Among the 19 leading exporting countries, the least incidences of bribe paying among companies to continue doing business in the country were in (in order) Sweden, Australia, Canada, Austria, and Switzerland, while the highest scores were for (in order) China, South Korea, Taiwan, Italy, and Malaysia. The sectors where bribery was likely to be more prevalent were (in order): Public works contracts and construction, Arms and defense industry (including petroleum and energy), Industry (including mining), Healthcare/social work, Telecommunications, Post (equipment and services), Civilian aerospace, Banking and finance, and Agriculture. Overall, almost a third of the respondents felt that corruption had increased over the past 5 years (i.e., 1994–1999).

Comparisons of BPI Scores Over Time

The BPI scores have remained consistent in some ways and changed in other ways between 1999 and 2011. Countries like Japan, the Netherlands, Switzerland, Belgium, and Germany are ranked with least bribes. There was no significant increase in the scores in the last two times the scores were published (i.e., between 2008 and 2011). The average score across the 22 countries in 2008 was 7.8, compared to a slightly higher rating of 7.9 in 2011.

By the final version of the BPI survey in 2011, a few things remained the same from the first study in 1999, while there were other notable differences. The data in 2011 were collected from more than 3000 business executives in 28 leading countries based on their value of their foreign direct investment (FDI) outflows, the value of their exports, and their regional significance. The Netherlands and Switzerland had the best scores, followed by Belgium, Germany, and Japan. Firms from these countries were seen to be least likely to engage in bribery than the other countries. At the bottom of the table, where business people perceived bribery to be the most widespread, were China and Russia, both of whom were substantially lower than the other surveyed countries. The remaining three countries rounding up the bottom five were Mexico, Indonesia, and the United Arab Emirates.

In looking at the change in scores on a country-by-country basis, no country's score has deviated by more than a point on the BPI. India saw a most significant increase of 0.7 yet remains in the bottom half of the table. Canada and the United Kingdom saw the most significant decreases in their scores with a decline of -0.3 each, which dropped their rankings by five and three places, respectively.

Recommendations

The BPI reports between 1999 and 2011 underlined the magnitude to which business professionals consider that bribery happens across major economies and business sectors. All

stakeholders, particularly governments and businesses, have to take responsibility for alleviating bribery practices. Governments should have effective regulatory policies installed in preventing as well as criminalizing bribery, as well as actively investigating and prosecuting bribery cases. Antibribery and anticorruption standards for suppliers and contractors in public procurement should be in place. Loan disbursements, as well as influencing bodies such as export credit agencies, should be carefully monitored.

Governments should also combat international bribery with international organizations such as the G20, European Union, UN, and the OECD. Countries should be encouraged to ratify the UN Convention against Corruption. Finally, international cooperation between regulators and enforcement agencies have to be strengthened to control bribery.

In addition to governments, the companies are also encouraged to bolster the implementation, monitoring, and reporting of anticorruption policies and procedures, and transparency commitments, which should be verifiable by independent third-party institutions. Firms should also be encouraged to report on how their anticorruption plans match global benchmarks, such as the UN Global Compact. They should also voluntarily disclose monetary transfers made to governments on a country-by-country basis and report all political contributions and lobbying efforts in their corporate reporting. Bribery and other corruption risks must be assessed not only within the firm but also across the entire supply chain. The antibribery policies must be clearly disclosed to suppliers, contractors, and other stakeholders. Finally, they should empower whistleblowers who have knowledge of bribery or corruption via appropriate policies and procedures.

Term and Definition

Bribery is a major aspect of the more generic term and concept of corruption. According to Transparency International, a worldwide operating NGO in the area of fighting corruption, established in 1993, corruption is the “the abuse of entrusted power for private gain or advantage” (Transparency International: <https://www.transparency.de/ueber-uns/was-ist-korruption/?L=0>) and bribery one of its best-known varieties.

In the legislation of most countries, the term “corruption” itself does not exist, only concrete types such as fraud, deception, extortion, or both, the active version of bribery in the form of offering someone an illegitimate advantage as well as the passive version in the form of taking this advantage (in German “Bestechlichkeit,” in English: corruptibility). Against this background, bribery can be defined as the act of offering/giving or accepting/receiving any item

of value with the purpose, implicitly or explicitly expressed by the active side (also referred to as the briber), of getting something in exchange which the passive party, the bribe-taker, otherwise would neither be willing nor allowed to give. (For a legal definition of bribery, see e.g., Articles 2 and 3 of the *Criminal Law Convention on Corruption (ETS 173)* of the Council of Europe; see also, the *United Nations Convention Against Corruption* (UN 2004), Articles 15 and 16, p. 17, for bribery in the private sector Article 21, p. 19.) The advantage, the actively bribing party is asking for, therefore, is an undue advantage.

As such, it has to be differentiated from offering money or gifts in order to get something, e.g., a service; the bribe giving side has a right to get respectively the receiving side is (legally) obliged to, such as clearing the goods for import at the border by public officials. In some countries, this practice is the norm, often resulting from a developing status not having the tax structure to pay civil servants an adequate salary. From an ethical viewpoint, this version of bribery has to be evaluated differently and, therefore, is often considered as belonging to the less immoral category of “petty corruption” (Pieth and Eigen 1999, p. 2). The given material advantage is also known as “facilitation payment,” “speed,” or “grease money.” (For different types of corruption and bribery, see e.g., Bannenberg (2002), pp. 111–114.) This differentiation is also reflected by some early legal frameworks in the area of anticorruption like the US Foreign Corrupt Practices Act from 1977: Even though formulating a clear and rather strict prohibition of “awarding contracts” by payments to foreign governments, it contains an exception regarding so-called grease payments, i.e., it allows companies payments to officials in order to obtain the performance of ministerial acts which they are legally required to do (Breslin and Kocoras 2010, p. 362).

These cases show at the same time that the active respectively passive sides of bribery are interchangeable: By demanding the undue advantage from the other side, the bribe-taker is taking over the active part.

Types of Bribes

Bribery occurs in many ways and takes many different forms (Breslin and Kocoras 2010, pp. 365/366). Primarily, material values are being offered by the briber respectively asked for by the other party. They may range from cash money, extra tip, precious gifts, invitations to expensive meals, events, or holidays, etc. via donations, the funding of research projects or political campaigns, sponsorships, etc. up to stock options or “special services” like building a swimming pool or a whole house for the bribe-taker. Bribery may also take the form of a secret commission, i.e., a profit made by an agent in the course of his employment without the knowledge of his principal. Euphemisms used for this are for instance “sweetener” or “kick-back” (Pieth and Eigen 1999, pp. 2–4).

Immaterial advantages can comprise a high rank position in the public or private sector, one’s vote in the next elections or championships, an attractive contract or any other version of promotion up to getting a better grade in an exam at university.

Unlike other forms of corruption, bribery only knows “offenders” since both sides take an advantage from the transaction whereas the “victims” resulting from this version of unethical or illegal behavior arise only outside of their relationship, i.e., among third parties like the community, the market, the rest of the affected organization. This, at the same time, makes the detection of bribery especially difficult because no side has an interest that the false behavior of any of the involved parties becomes evident. According to experts in the field, the most important factor to prevent bribery, thus, is both, a culture as well as structures fostering the principles of transparency and of equality! (see e.g., Bannenberg and Schaupensteiner 2004).

Reasons for and Consequences of Bribery

Bribery takes place at all institutional levels and in all areas of society: Politics, sports, medicine, business, etc. Next to structural reasons like a

lack of transparency, cultural or historical reasons like in China, e.g., the tradition of operating in closely connected networks, the so-called *guanxi* (see e.g., Chen 2004, pp. 62–64), bribery in principle is favored by any kind of imbalance of power or influence in a specific context. This may be true for a policeman in the situation of stopping a driver who didn't obey the rules, for the referee in a soccer match as final decision-maker for imposing a sanction to one of the teams, for the doctor who can prescribe to his patients the products of a certain pharmaceutical company only, or for the purchaser of a private or public organization who decides about contracts and tenders. In all of these examples, there is a potential risk that an interested party tries to influence the respective persons by offering them a monetary or immaterial bribe to either avoid negative consequences for itself or to achieve an individual advantage.

In a broader societal, political, and economic context, the widespread practice of bribery often goes along with low life expectancy, poverty, poor health, and unequal distribution of income and wealth rooted in dysfunctional public and private institutions (see e.g., Frisch 1999; Rose-Ackerman 1999). Because of unfair competition, its distortion, or, in some cases, even its full extinction, consumers as well as customers in the B-to-B-sector will have to buy overpriced products of a bad quality. As a result, affected countries and their economies are unable to use their potential, e.g., human and material resources, effectively. Inefficient companies and the allocation of talent, technology, and capital away from their most productive uses lead to further economic losses (Frisch 1999, p. 93; Cockcroft 2012, p. 135). Entrepreneurs entering the market will face a corrupt structure of making deals and be forced to bargain over bribes which will minimize their incentives to enter the market at all. Consequences include greater political instability, international distrust, less direct foreign investments, less national output and organizational growth, lower tax income as well as lower levels of public spending on education and health care (Rose-Ackerman 1999, p. 42). It is precisely this vicious circle that explains why corruption

and bribery are seen as one of the largest obstacles for the healthy and sustainable development of countries (Frisch 1999, pp. 92–94; Redwitz 2013, p. 7).

The correlation described above is also reflected by the annually published “Corruption Perception Index” of Transparency International in which Scandinavian countries with a comparably high average income, a high standard of living, and a high degree of public transparency are always listed on the first ranks indicating a low rate of perceived corruption (see e.g., Transparency International 2019).

Relevance in the Context of Sustainable Management

As the previous section shows, bribery has a significant negative impact on the economy and on the well-being of societies and their people. Fighting bribery, as a major version of corruption, thus, can be seen as a significant factor on the way to sustainable development of the global society.

In 2015, this overarching global goal has been made more concrete by the new “Agenda 2030” of the United Nations, consisting of 17 so-called Sustainable Development Goals (SDGs) including 169 targets. Unlike the UN Millennium Development Goals, the new SDGs are not only addressing states and governments of the developing world; all countries and all kinds of organizations worldwide are equally appealed to contribute to the realization of the Agenda 2030 (UN 2015: Article 67 of the Agenda 2030).

Next to other international frameworks or global “soft law,” relevant for sustainability, like the OECD guidelines, the 10 Principles of the UN Global Compact, or ISO 26000, the SDGs, therefore, can be considered as today's main framework and scale for sustainability and the sustainable management of organizations.

Against the background of the negative consequences of bribery described above, especially, the following goals implicitly recommend to take efforts to stop bribery and corruption inside and outside of organizations:

Goal no. 8	<i>Promote sustained, inclusive, and sustainable economic growth, full, and productive employment, and decent work for all</i>
Goal no. 10	<i>Reduce inequality within and among countries</i>
Goal no. 12	<i>Ensure sustainable consumption and production patterns</i>

Explicitly, Goal no. 16 is addressing the fight against corruption and bribery: “Promote just, peaceful, and inclusive societies” (UN 2015: Goal 16), in particular, by target 5: *Substantially reduce corruption and bribery in all their forms* and by target 6: *Develop effective, accountable and transparent institutions at all levels*.

Global and Legal Approaches to Fight Bribery in and of Organizations

Apart from the Foreign Corrupt Practices Act (FCPA) of the United States from 1977 (see also above), which addressed the influencing of foreign officials by companies through rewards or payments, other countries came up with comparably strict legislations much later – in many cases as a reaction to spectacular fraud and corruption scandals (e.g., Siemens in Germany) or in order to support fair competition on a global market and to encourage foreign investments (like in China after 1997) (see e.g., Schroeder 2009, pp. 55–57).

International institutions like the OECD and the UN started in the 1990s to encourage the fight against bribery and corruption by guidelines, conventions, and voluntary agreements for both, countries and businesses: In 1996, the OECD council recommended to member countries to refrain from the tax-deductibility of bribes to foreign officials (which happened, e.g., in Germany not before 2002), followed by the publication of their Anti-Bribery Convention (“Convention on Combating Bribery of Foreign Public Officials in International Business Transactions”) (OECD 2009). It was signed in December 1997 and came into force in February 1999. Against the background of the UN’s preparation of a respective convention, in 2003, the UN Global Compact

added to the originally 9 principles from 1999, a 10th principle regarding antibribery, and finally, in 2004, the United Nations released their “United Nations Convention against Corruption (UNCAC),” considered by the editing office (UN office on drugs and crime) as the “only legally binding universal anti-corruption instrument” (United Nations 2004). Next to the description of preventive measures, criminalization and law enforcement, international cooperation, asset recovery, etc., it covers many different forms of corruption, such as bribery, trading in influence, abuse of functions, and various acts of corruption in the private sector.

Till date, the UK Bribery Act (2010), which came into effect in 2011, is considered as one of the strictest laws in the area of antibribery. In effect, it owns a global scope of application as it governs not only the British companies but all their subsidiaries as well. The UK’s authorities aggressively pursue offenders regardless of their geographical location or place of incorporation, following the so-called Long Arm of the Law principle. After its establishment, the UK’s Ministry of Justice at that time indicated that all that is required to be subject to the UK’s new law is considered to be a tangential relationship with the UK, falling, thus, under its scope. Offences may lead to sanctions of both, individuals and corporates, including high financial fines and/or imprisonment of individuals up to 10 years (Breslin and Kocoras 2010, pp. 363–365).

In the case of sentencing, the FCPA as well as the UK Bribery Act are rewarding the efforts of organizations to prevent bribery on a corporate level, by less strict sanctions. Systematic approaches which include antibribery measures are known today as compliance and/or integrity programs.

Corporate Approaches of Preventing Bribery: Compliance- and Integrity Management

As a reaction to the huge fraud scandal around the US-American energy company Enron, the United

States published a new law in 2002, the Sarbanes Oxley Act (SOX) which made compliance and compliance management mandatory for all companies worldwide if they want to be listed at any stock exchange located in the United States. Until then in Europe, only the financial sector had heard of and practiced “compliance” in a corporate context (Kleinfeld and Martens 2018, p. 6).

In the Business Ethics debates in the United States and in Europe, however, a discussion about compliance as a minimum requirement of corporate ethical behavior had already taken place in the 1990s, going along with the controversial discussion of whether the so-called integrity approach (see e.g., De George 1993; Paine 1994; Becker 1998), based on a management of values, of corporate culture and on the intrinsic motivation and commitment of the corporate members, would be the more effective alternative to a pure compliance approach, concentrating on controlling mechanisms of legal conformity only (Kleinfeld and Martens 2018, p. 7; Schöttl 2018, pp. 38–41). Both, the theoretical discussion as well as the later introduced practical approaches of compliance and/or integrity management had a strong focus on preventing bribery and other forms of corruption in and of organizations – the latter mainly because of the new legal frameworks described above.

In the meantime, a number of national as well as international guidelines and standards have been developed providing guidance for companies of the private and public sector how to set up, establish and manage effective antibribery measures inside, as a part of their own corporate governance mechanisms, but also outside, throughout their supply and value chains. One of the first globally promoted frameworks were the *Business Principles for Countering Bribery* by Transparency International (2002), published in a first edition in December 2002. The principles could be used both, for the orientation of the own bribery preventing activities, as well as for external verification processes in order to assure that an organization has established a program which is considered to be state of the art in the field of antibribery.

Defining what precisely is state of the art in a certain area on a global scale is one of the main tasks of the International Standards Organization (ISO): In 2014, it published ISO 19600, a guidance document dealing with the implementation and establishment of an effective compliance management; in 2016, it released ISO 37001, a certifiable standard which “specifies requirements and provides guidance for establishing, implementing, maintaining, reviewing and improving an antibribery management system” (ISO 2016). Verification processes based on ISO 37001 or any other certifiable framework, however, cannot and never are intended to guarantee that an organization and all of its members are behaving with integrity. The main reason for companies to undergo an external verification process of their antibribery programs instead is to credibly show to customers or public authorities that they did respectively are doing whatever necessary to prevent bribery.

Against the background of the legislation and its sentencing guidelines described above, this becomes especially relevant in the event of a concrete case of bribery or any other form of corruption.

Brundtland Report

Dirk Reiser

Faculty of Society and Economics, Rhine-Waal
University of Applied Sciences, Kleve, Germany

Synonyms

[Our common future](#)

Definition

The 12 chapters (247 pages) Brundtland report was published by the United Nations World Commission on Environment and Development (UNWCED) in 1987. Its title is derived from the name of the head of the commission, Gro Harlem Brundtland. Its original title is “Our common future.” The report aims to provide a perspective for the long-term, environmentally-friendly, and sustainable human development (Raschke 2015) to address international environmental concerns about economic development (Quick 2017).

History and Description

The Brundtland report counts as the beginning of the discourse about sustainability and sustainable development, but the discussion about the topic started at least in 1972 with the publication of the report “Limits to growth” by the Club of Rome and the United Nations Conference on the Environment in Stockholm (BMZ 2020). It continued in the early 1980s, as the United Nations became highly concerned about the deterioration of natural resources and the human environment, including ozone depletion, global warming, and the unequal living standards of the world population (Britannica 2020).

On the 19th of December 1983, the General Assembly of the United Nations therefore agreed on the establishment of a special commission (Resolution 38/161) to make a report on the environment and global problems to the year 2000 and beyond available. A particular focus was to be put on proposed strategies for sustainable development (United Nations 2020). The UN expected that the commission would develop a “Global Agenda for Change.” Included in this resolution was the point that the report shall collaborate with the Intergovernmental Inter-Sessional Preparatory Committee of the Governing Council of the UN Environment Program to provide the basis for the environmental perspective of the United Nations Environment Program (UNEP) up to the year 2000. More specifically, the General Assembly called the Commission:

- “To propose long-term environmental strategies for achieving sustainable development by the year 2000 and beyond;
- To recommend ways concern for the environment may be translated into greater co-operation among developing countries and between countries at different stages of economical and social development and lead to the achievement of common and mutually supportive objectives that take account of the interrelationships between people, resources, environment and development;
- To consider ways and means by which the international community can deal more effectively with environmental concerns; and
- To help define shared perceptions of long-term environmental issue and the appropriate efforts needed to deal successfully with the problems of protecting and enhancing the environment, a long term agenda for action during the coming decades, and aspirational goals for the world community.” (WCED, 1987, Foreword by Brundtland)

The UN Secretary General Javier Perez de Cuellar appointed the commissioners of the UNWCED, chairwoman Gro Harlem Brundtland (Norway) and vice chairmen Mansour Khalid (Sudan). They selected the members of the commission from elected and civil servants as well as environmental experts from the 21 participating

countries. It consisted of 19 members from 19 countries (originally 20 members from 20 countries): Susanna Agnelli (Italy), Saleh A. Al-Athel (Saudi-Arabia), Bernard Chidzero (Zimbabwe), Lamine Mohammed Fadika (Cote d’Ivoire), Pablo Gonzales Casanova (Mexico, left the commission in August 1986 for personal reasons), Volker Hauff (Federal Republic of Germany), Istwan Lang (Hungary), Ma Shijun (People’s Republic of China), Margarita Marina de Botero (Colombia), Nagendra Singh (India), Paulo Nogueira-Neto (Brazil), Saburo Okita (Japan), Shridath S. Ramphal (Guyana), William Doyle Ruckelshaus (USA), Mohamed Sahnoun (Algeria), Emil Salim (Indonesia), Bukar Shaib (Nigeria), Vladimir Sokolov (USSR), Janez Stanovnik (Yugoslavia), Maurice Strong (Canada), plus Jim MacNeill (Canada; ex officio). The Commission was an independent body, where the members served as individuals and not as representatives of their governments.

In the year 1987, the commission released its report “Our common future”. It was the conclusion of 4 years of discussions about the future of humanity. The publication of the report resulted in two following international conferences on the importance of global sustainable development in London in 1987 and in Milano in 1988. The commission was officially dissolved on 31.12.1987, but continued as the Centre for Our Common Future in Geneva in April 1988. It was re-activated as part of the Rio-Conference in 1992 (Lexikon der Nachhaltigkeit 2020). At this conference (also called Rio Earth Summit), the directives from the Brundtland Report were expanded into five agreements including the Rio Declaration on Environment and Development and Agenda 21 (Quick 2017). The ideas of the report are also included in the Millenium Development Goals and the Sustainable Development Goals (SDGs) (Mondini 2019).

The book is subdivided into three parts and 12 chapters. It covers topics such as sustainable development, energy consumption, industrial impacts, impacts species and ecosystems, the role of the international economy for development, population growth and human resources, food security, and legal principles for environmental protection (Britannica 2020). In more detail, the report contains the following parts and chapters:

Part 1 Common Concerns (Chap. 1 A threatened future; Chap. 2 Towards Sustainable Development, Chap. 3 The Role of the International Economy).

Part 2 Common Challenges (Chap. 4 Population and human resources; Chap. 5 Food Security: Sustaining the Potential; Chap. 6 Species and Ecosystems: Resources for Development; Chap. 7 Energy: Choices for Environment and Development; Chap. 8 Industry: Producing More with Less; Chap. 9 The Urban Challenge).

Part 3 Common Endeavors (Chap. 10 Managing the Commons; Chap. 11 Peace, Security, Development, and the Environment; Chap. 12 Towards Common Action: Proposals for Institutional and Legal Change) (UNWCED 1987)

One of the most enduring aspects of the publication is the popularization of the following definition of sustainable development as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs. It contains within it two key concepts:

- the concept of ‘needs’, in particular the essential needs of the world’s poor, to which overriding priority should be given; and
- the idea of limitations imposed by the state of technology and social organization on the environment’s ability to meet present and future needs” (UNWCED 1987, p. 41)

For the first time, “Our common future” made available a basis for integrative global policies that connected usually separated problem areas such as environmental pollution in industrialized countries, debt crisis, population development, and desertification in the so-called third world. The goals were to overcome poverty in the developing world and adjust consumption patterns in the industrialized world with the protection of nature as the foundation of human life (Lexikon der Nachhaltigkeit 2020). At the same time, critics argued that the report reflects a continued believe in the ideals of economic growth to sustain the status quo, thereby securing the ability of humanity to develop within the existing socio economic mechanisms through a different type of growth (Hopwood et al. 2005; Cayley n.d.). Additionally,

the concept of needs as an anthropocentric term allowing the instrumental use of nature, the question of what should be developed and sustained as well as the lack of models to operationalize the vague definition of sustainable development (e.g., quantification and qualification) are further shortcomings. Today, the use of the expression sustainable development is used in ways that sometimes mutually exclusive (Redclift 2009). At the same time, it was outlined that “Our common future” provides a pragmatic reform approach, accepting the necessity of new ways to interact with the environment as being interconnected with the economy and the society (Cayley n.d.).

Since the publication of the report, the world has changed dramatically (e.g., the end of the Cold War, globalization, neo-liberal economic changes) and with it subsequent interpretations of the concept of sustainable development (Papuzinski 2018). Nevertheless, the Report brought sustainability issues into the mainstream (Cayley n.d.). Moreover, it gives the first systematization and reference of the link of development and environmental issues and the connection of the responsibility of present generations for future generations (Reschke 2015).

The complete report can be downloaded on: <https://sustainabledevelopment.un.org/milestones/wced>

Summary

The 1987 published so-called Brundtland Report (Our common future) by the UNWCED was an important step in the public discourse on sustainable development. It continued a process that had started in 1972 at the United Nations Conference on the Environment in Stockholm and later continued at the Rio Earth summit in 1992. Today, it remains a valid base for global sustainable development expressed, for example, in the Sustainable Development Goals. (This comes from the original text) Since the publication of the 12-chapter report, the world has changed dramatically (e.g., the end of the Cold War, globalization, neo-liberal economic changes) and with it subsequent interpretations of the concept of sustainable development (Papuzinski 2018).

Nevertheless, the Report brought sustainability issues into the mainstream (Cayley n.d.). Moreover, it gives the first systematization and reference of the link of development and environmental issues and the connection of the responsibility of present generations for future generations (Reschke 2015).

BS8001 Circular Economy Standard

Synonyms

Circular economy best practices; Circular economy guidelines; Circular Economy

Implementation Standards; Circular Economy Sustainability Standards

Definition

The circular economy is a holistic systems approach that looks to create a closed loop of material flows, where waste is minimized, and products and materials are kept in use for as long as possible. BS8001: Circular Economy Standard is a framework developed by the British Standards Institution (BSI) to help organizations implement circular economy principles and practices. The standard provides guidance on how to assess an organization's circular economy performance, how to identify and manage material flows, how to use renewable energy and reduce greenhouse gas emissions, and how to promote social fairness and well-being. The standard is intended to help organizations reduce their environmental impact and improve their economic performance by creating new business opportunities, driving innovation, and increasing resource productivity. BS8001 serves as a guide to organizations on how to implement the circular economy principles; it provides a set of guidelines and requirements that organizations can follow to improve their environmental performance, economic performance, and social performance. The standard can be applied to organizations of all sizes and sectors, it is intended to help organizations to adopt the circular economy principles and create a more sustainable future.

Introduction

The circular economy is a concept that has gained significant attention in recent years as a way to address the pressing environmental and economic challenges of our time. The traditional linear model of take-make-waste, in which resources are extracted, used, and then discarded, is no longer sustainable. Instead, the circular economy aims to keep resources in use for as long as possible, extracting the maximum value from them before recovering and regenerating them (Wiedmann et al. 2018). This approach can not

only reduce the environmental impact of economic activity but also improve economic performance by creating new business opportunities, driving innovation, and increasing resource productivity (Elegbede et al. 2023a, b; Easton et al. 2017).

The circular economy is a holistic systems approach that seeks to create a closed loop of material flows, where waste is minimized, and products and materials are kept in use for as long as possible. This can be achieved through the implementation of circular economy principles, such as designing out waste and pollution, keeping products and materials in use, and regenerating natural systems (European Commission 2015).

One of the key ways to implement the circular economy is through the use of standards and frameworks. The British Standards Institution (BSI) developed BS8001, which provides a framework for organizations to implement circular economy principles and practices. BS8001 is a standard that is designed to help organizations to improve their environmental performance, economic performance, and social performance (BSI 2020). It provides guidance on how to assess an organization's circular economy performance, how to identify and manage material flows, how to use renewable energy and reduce greenhouse gas emissions, and how to promote social fairness and well-being (Chen et al. 2019).

Principles of the Circular Economy

The circular economy is based on a set of principles that aim to create a closed loop of material flows, where waste is minimized, and products and materials are kept in use for as long as possible. The principles of the circular economy include designing out waste and pollution, keeping products and materials in use, and regenerating natural systems (Ellen MacArthur Foundation 2018, 2019).

Designing out waste and pollution: The circular economy seeks to design out waste and pollution by creating products and services that are designed for disassembly and reuse, and that minimize the use of hazardous materials. This can be achieved through the use of life cycle thinking,

which considers the entire life cycle of a product or service, from design and production to use, reuse, and end-of-life (Ellen MacArthur Foundation 2018).

Keeping products and materials in use: The circular economy aims to keep products and materials in use for as long as possible by extending their lifetimes, and by recovering and regenerating materials at the end of their useful lives. This can be achieved through the use of circular business models such as product-as-a-service, leasing, and shared use (Kestens et al. 2018).

Regenerating natural systems: The circular economy also aims to regenerate natural systems by reducing the use of virgin materials and increasing the use of renewable materials. This can be achieved through the use of closed-loop systems, such as recycling, composting, and anaerobic digestion, that convert waste into valuable resources (Elegbede et al. 2022; Ellen MacArthur Foundation 2018). It is important to note that the circular economy principles are interconnected and mutually reinforcing, and that the implementation of one principle often supports the implementation of others (Ellen MacArthur Foundation 2018).

BS8001 Requirements and Implementation

BS8001 is a standard developed by the British Standards Institution (BSI) to provide a framework for organizations to implement circular economy principles and practices. The standard is intended to help organizations reduce their environmental impact and improve their economic performance. The standard is composed of three key requirements: assessment, management, and performance.

Assessment: BS8001 requires organizations to assess their circular economy performance by identifying and quantifying the material flows that are most relevant to their operations. This assessment should take into account the entire life cycle of the products and services, from raw materials to end-of-life (BSI 2017, 2020).

Management: BS8001 requires organizations to manage their material flows by developing

strategies and action plans to reduce waste, increase resource efficiency, and promote the use of renewable materials. This can be achieved through the use of circular business models such as product-as-a-service, leasing, and shared use (Kestens et al. 2018).

Performance: BS8001 requires organizations to continuously monitor and improve their circular economy performance by setting targets and indicators, and by reporting their progress to stakeholders (BSI 2020).

Implementation: Implementing BS8001 requires organizations to take a holistic approach that considers the entire life cycle of products and services. Organizations should begin by assessing their circular economy performance, identifying the material flows that are most relevant to their operations. This assessment should take into account the entire life cycle of the products and services, from raw materials to end-of-life (BSI 2020).

Once the assessment is completed, organizations should develop strategies and action plans to reduce waste, increase resource efficiency, and promote the use of renewable materials (Kestens et al. 2018). This can be achieved through the use of circular business models such as product-as-a-service, leasing, and shared use. Also, organizations should continuously monitor and improve their circular economy performance by setting targets and indicators, and by reporting their progress to stakeholders (BSI 2020).

An example of an organization implementing BS8001 is a car manufacturing company that switches to a product-as-a-service business model by leasing cars to customers instead of selling them. By doing so, the company is able to reduce waste by keeping cars in use for longer periods of time, increase resource efficiency by using renewable materials in the manufacturing process, and promote the use of renewable energy by encouraging customers to use electric cars. Another example of an organization implementing BS8001 is a construction company that switches to using circular building materials such as reclaimed wood and recycled steel in their building projects. By doing so, the company is able to reduce waste by using materials that would

otherwise go to the landfill, increase resource efficiency by using materials that have already been extracted and processed, and promote the use of renewable materials by using materials that can be recycled or regenerated at the end of their useful life. It's worth noting that the examples above are just a representation of how organizations can implement BS8001. Every organization will have different challenges and opportunities to apply the standard in their specific field.

Effectiveness of BS 8001:2017 Circular Economy Standard for Organizations

The Circular Economy Standard for Organizations BS 8001:2017 is a comprehensive guide to the implementation of circular economy principles in organizations. The standard provides an in-depth introduction to the motivations behind the circular economy, its mechanisms, and its relation to other concepts such as resource efficiency and the bioeconomy. The standard defines the circular economy as an “economy that is restorative and regenerative by design, and which aims to keep products, components, and

materials at their highest utility and value at all times, distinguishing between technical and biological cycles.” The definition of value in the standard is described as “financial and/or non-financial gain” (Pauliuk 2018).

The standard lists several macro-level benefits of the circular economy, including improved resilience of economic systems, economic growth and employment, and preserved natural capital and climate change mitigation. At the micro-level, the standard cites cost savings, new sources of innovation and revenue, improved customer relationships, and improved resilience for organizations as benefits (Fig. 1).

The standard outlines six principles of the circular economy that all organizations should follow, with systems thinking and stewardship being two overarching principles that have far-reaching consequences for decision-making within the organization. The core of the standard is an eight-stage flexible framework to guide the practical implementation of circular economy principles in organizations. The framework is flexible, allowing organizations to adapt it to their level of “circularity maturity.”

For each stage, the standard provides a detailed description of its purpose and the actions that

BS8001 Circular Economy Standard, Fig. 1 Framework and key components of the BS 8001:2017 Circular Economy Standard for Organizations (Pauliuk 2018)

should be taken, with a review of the outcome against the principles of the circular economy. The standard also provides guidance on business models, enabling mechanisms, and a total of 16 circular economy issues and considerations, including aspects of accounting, competition law, marketing, insurance, and information management. The overarching goal of the implementation of circular economy principles is to create long-term business value through sustainable resource management (Pauliuk 2018).

The standard contains a warning against superficial adoption of circular economy principles and emphasizes the need for systemic consideration in order to create real change towards a circular economy. The standard's strengths include the clarification of terms, the description of the profound changes necessary, the integration of circular economy principles into the business development process, and the description of relevant regulatory frameworks and mechanisms. However, there may be some tension between the need for radical change and the standard's main task of providing reliable and authoritative guidance on organizational processes.

Overall, the Circular Economy Standard for Organizations BS 8001:2017 serves as a comprehensive guide to the implementation of circular economy principles in organizations, providing a flexible framework, clear guidance on business models and enabling mechanisms, and the integration of circular economy principles into the business development process.

Circular Economy Business Models

Circular economy business models are a key element of the circular economy as they can provide organizations with new opportunities to create value while reducing their environmental impact. Circular economy business models can be defined as “innovative business models that are designed to keep products, components, and materials at their highest utility and value at all times, in a closed loop system” (Kestens et al. 2018).

There are several different types of circular economy business models, each with its own

unique characteristics. Some of the most common circular economy business models include:

Product-as-a-service: This model involves providing customers with access to a product rather than selling the product itself. This can be achieved through leasing, renting, or subscription-based models. An example of a product-as-a-service model is a car sharing program, where customers pay a monthly fee for access to a fleet of cars rather than purchasing a car (Geyer et al. 2017).

Shared use: This model involves sharing resources, such as equipment or facilities, among multiple users. An example of a shared use model is a tool sharing program where customers can borrow tools from a community-based lending library rather than purchasing their own tools (Hammer 2018).

Closed-loop supply chains: This model involves creating closed-loop systems where resources are kept in use for as long as possible and waste is minimized. An example of a closed-loop supply chain model is a recycling program where waste materials are collected, processed, and used as raw materials for new products (Lieder et al. 2018).

Upcycling: This model involves taking waste materials and turning them into new products of higher value. An example of upcycling is turning used plastic bottles into fibers for clothing (Lieder et al. 2018).

Leasing: This model involves renting out a product or service for a certain period of time, at the end of which the product is returned to the supplier. An example of leasing is renting out construction equipment instead of buying it (Geyer et al. 2017).

Circular economy business models can provide organizations with new opportunities to create value while reducing their environmental impact. They can also help organizations to comply with BS8001 requirements by reducing waste, increasing resource efficiency, and promoting the use of renewable materials (Tiwari et al. 2019). Additionally, these business models can also help organizations to improve their economic performance by creating new revenue streams and reducing costs (Geyer et al. 2017).

However, it is important to note that implementing circular economy business models can also present challenges for organizations. These challenges include a lack of understanding and knowledge about circular economy business models, limited access to financing and investment, and regulatory barriers (Hammer 2018).

To successfully implement circular economy business models, organizations must have a clear understanding of the circular economy principles and the potential opportunities and challenges that these models present. They should also actively engage with stakeholders and partners to build a supportive ecosystem and overcome any barriers to implementation (Hammer 2018).

Challenges and Opportunities of Implementing BS8001

Implementing BS8001, the Circular Economy Standard developed by the British Standards Institution (BSI), can provide organizations with numerous benefits, including improving resource efficiency, reducing waste, and promoting the use of renewable materials. However, the implementation process can also present various challenges for organizations.

One major challenge is a lack of understanding and knowledge about circular economy principles and practices. This lack of understanding can make it difficult for organizations to identify and implement relevant circular economy strategies and action plans (Hammer 2018). Additionally, organizations may face limited access to financing and investment for circular economy projects and initiatives, particularly for small and medium-sized enterprises (SMEs) (Geyer et al. 2017).

Regulatory barriers can also pose a challenge for organizations looking to implement BS8001. Regulations and policies that are not aligned with the principles of the circular economy, such as those that favor a linear take-make-waste model, can hinder the implementation process (Hammer 2018). Moreover, organizations may also face resistance to change from employees, customers, and other stakeholders who may be hesitant to embrace new circular economy practices and business models (Hammer 2018).

Despite these challenges, there are also many opportunities for organizations that implement BS8001 and adopt circular economy principles and practices. These include:

Creating new business opportunities: Organizations can create new revenue streams and business models by implementing circular economy principles and practices (Geyer et al. 2017).

Driving innovation: Organizations can drive innovation by finding new ways to use resources and by developing new products and services (Tiwari et al. 2019).

Reducing costs: Organizations can reduce costs by improving resource efficiency and by reducing the need to purchase new raw materials (Geyer et al. 2017).

Improving environmental performance: Organizations can improve their environmental performance by reducing waste, increasing resource efficiency, and promoting the use of renewable materials (Tiwari et al. 2019).

Improving social performance: Organizations can improve their social performance by creating sustainable jobs, promoting fair labor practices, and fostering collaboration between different stakeholders (Hoffman 2019).

Best Practices for Implementing BS8001

Implementing BS8001 can be a complex process, but there are several best practices that organizations can follow to ensure a successful implementation.

Assess current performance: Organizations should assess their current performance related to circular economy principles and practices, and identify areas for improvement. BS8001 provides a framework for assessing circular economy performance, including environmental performance, economic performance, and social performance (British Standards Institution 2020).

Develop a strategy and action plan: Organizations should develop a strategy and action plan that outlines specific actions to be taken to improve circular economy performance. The strategy and action plan should align with the organization's overall sustainability goals and objectives (British Standards Institution 2020).

Engage stakeholders: Organizations should engage with stakeholders, including employees, customers, suppliers, and other partners, to build support for the implementation of BS8001. Stakeholder engagement can also help organizations identify challenges and opportunities, and identify potential solutions (British Standards Institution 2020).

Continuously monitor and improve performance: Organizations should continuously monitor and evaluate their circular economy performance, and take actions to improve performance as needed. BS8001 includes requirements for monitoring and reporting on circular economy performance (British Standards Institution 2020).

Leverage technology: Organizations can leverage technology to improve resource efficiency, increase the use of renewable materials, and reduce waste. Examples of technologies that can be used to support circular economy principles include digital platforms for sharing resources, recycling technologies, and circular design software (British Standards Institution 2020).

Collaborate with other organizations: Organizations should collaborate with other organizations to share knowledge, resources, and best practices related to circular economy principles and practices. Collaboration can help organizations to overcome challenges and achieve greater impact (British Standards Institution 2020).

Summary

BS8001 provides a framework for organizations to implement circular economy principles and practices and improve their environmental performance, economic performance, and social performance. The standard requires organizations to assess their circular economy performance, develop strategies and action plans to reduce waste, increase resource efficiency, and promote the use of renewable materials, and continuously monitor and improve their performance. By implementing BS8001, organizations can create new business opportunities, drive innovation, and increase resource productivity while reducing their environmental impact. Circular economy

business models are an essential element of the circular economy as they can provide organizations with new opportunities to create value while reducing their environmental impact. Organizations should consider implementing these models as part of their efforts to comply with BS8001 and create a more sustainable future. Implementing BS8001 can present challenges for organizations, the benefits of improved resource efficiency, reduced waste, and increased use of renewable materials make it a worthwhile endeavor. Organizations should carefully evaluate the challenges and opportunities and develop strategies to overcome the challenges and capitalize on the opportunities. Implementing BS8001 requires a comprehensive approach that includes assessing current performance, developing a strategy and action plan, engaging stakeholders, continuously monitoring and improving performance, leveraging technology, and collaborating with other organizations. By following these best practices, organizations can improve their circular economy performance and achieve their sustainability goals.

Building Energy Management

Ayça Tokuç

Dokuz Eylül University, İzmir, Turkey

Synonyms

Building energy conservation; Building energy management system (BEMS); Building management

Definition

Building energy management is the act of energy conservation in a building through identifying and monitoring energy consumption and directing building and user behavior to decrease energy consumption and costs. From a wider point of view, the term also pertains to energy policy targets like zero emissions, decreasing air pollution, increasing the share of renewable energy resources, or creating smarter cities. Building management and building energy management is mainly threefold. First is the physical and energetic aspects of management, which is affected by the design, size, age and use of the building, energy-consuming equipment located inside of the building, monitoring equipment, sensors, control mechanisms, and other physical makeup of the building. Second is decreasing energy costs, which is usually a significant part of the operational budget. This aspect is concerned with how the building is connected to the infrastructure, its

access to renewable energy resources, and contracts with utility companies. The third is engaging with tenants and managing or encouraging pro-environmental behavior. The responsibility of management lies with both a building manager and whoever is driving the development in the city, thus directing the vision and consequent management decisions related to energy policy and infrastructure. A more limited view of building energy management is the utilization of only Building Energy Management Systems (BEMS). BEMS and other advances in technology make monitoring, adjusting and implementation easier while decreasing energy consumption and costs. They can also be integrated to control other systems such as water, industrial processes, security, and information.

Background

The building sector accounts for about 20% of the total delivered energy consumption in the world (EIA 2019), and in many countries, the building sector consume around 40% of the total energy use in the EU and 37% in China (Delzendeh et al. 2017). In addition, this consumption constitutes about one-third of global carbon emissions (UNEP 2009), therefore decreasing building energy consumption is a common target in decreasing carbon emissions to mitigate climate change. However, the total building energy demand is estimated to increase because of growth (EIA 2019) that is an increase in the human population, quality of life, and access to services. In this context, all countries and many regions have legislation and aims relevant to building design and construction. For example, the recast of EU's Directive on Energy Performance of Buildings in 2017 establishes "nearly zero energy building" as the target for all public buildings after 2018 and all new buildings after 2020 at the European level. In the USA, voluntary practices and programs that encourage energy-efficient structures are widespread, one of which is the Zero Energy Ready Homes program of the US Department of Energy. Moreover, concerned parties are creating more stringent or voluntary building

initiatives such as green building, solar building, zero energy building, plus energy building, energy-efficient building, passive building, zero-emission building, intelligent building, and smart building. Besides, decarbonization of a building, which means removing greenhouse gasses from the buildings' energy consumption, is a long-term goal.

After the industrial revolution, new building typologies such as factories, apartments, and skyscrapers have emerged, and urbanization has accelerated and created a change in both the citizen culture and the building stock. Also, modern architecture, which advocates that people should dominate the nature and that a building can be applied anywhere regardless of local environmental conditions, has emerged and spread globally, thus utilizing heating and cooling systems to regulate environmental conditions and reach thermal comfort conditions while consuming huge amounts of energy became the norm. The energy crisis of the 1970s became a wakeup call to the unsustainability of this system; moreover, environmental awareness increased. With increasing awareness of environmental impacts of greenhouse gas emissions resulting from energy use, the concepts of energy efficiency and energy management in buildings gained importance. Nevertheless, the consumption society and the associated consumption-based building construction still remained largely dominant.

The energy policy and targets of a city or a nation are affected by the building stock and its energy consumption to a certain degree (see, for example, Dhakal 2009). In this context, data about the existing situation can be collected from resources such as building permits, demographics, geographical information systems (GIS), energy use, and energy audits or assessments. Scenarios can be developed by answering the questions of "which buildings," "which technologies," "which policies," and "who pays." When gaps are identified, decisions can be made related to the targets of energy policy like zero emissions, decreasing air pollution, increasing the share of renewable energy resources, decreasing costs, or creating smarter cities. The partners include building owners, developers, contractors,

Building Energy Management, Fig. 1 Conceptual diagram of building energy management

investors, local authorities, utilities, and companies. Thus implementation, that is, building energy management, usually becomes a step in the continuing progress toward reaching large-scale goals, yet the implementation can be divided into application steps of physical aspects, decreasing energy costs, and social engagement (Fig. 1).

Physical Aspects

The main factors in reaching comfort and minimum energy consumption in a building are the building's design and its physical properties. The major energy consumption categories of a building are usually determined at the design phase, and are related to heating, cooling, ventilation, water heating, electrical appliances, and cooking. Accordingly, the energy performance of a building depends on its architectural, and mechanical and electrical-electronic systems design. Passive and active technologies and design strategies are mainly concerned with appropriate architectural

design, integration of renewable energy resources within buildings, proper design, and choice of technical equipment for thermal, visual, and acoustic comfort. The main considerations for energy efficiency include orientation; relationship with other buildings and infrastructure; construction details; the utilization of surrounding sources from the sun, wind, light, air, water, and ground; the life cycle energy requirements and thermo-physical properties of building materials; and using energy-efficient appliances. Contemporary building regulations usually limit the maximum values for energy consumption related to heating and cooling requirements. In addition to calculations to show compliance with building codes, building simulation and building information modeling in the design stages can help to significantly increase building energy performance (see Fouquier et al. 2013, for more information). However, the occupants and manager of the building play a role in the actual performance of the building and actual results can show (sometimes up to three times) higher values for total energy

consumption, or even larger (e.g. up to ten times) values for energy end-use (Hong et al. 2016).

After the major energy consuming activities are identified, they can be monitored through metering, sensors, or utility bills. The role of sensors is important for an efficient and reliable system. Environmental sustainability is an important issue today; therefore sensors monitor the operation of environmental elements. Some of the sensors are level indicators of clean water tanks, gray water tanks and rainwater tanks, rain sensors for operations such as plant irrigation, and photovoltaic cleaning in the water systems. Other sensors include photometers, light adjustment, human presence, wind, smoke, electricity production and consumption, and electrical measuring devices consumed by different devices in the electrical installations. In this context, occupancy and behavioral patterns can be deduced by new algorithms.

Design strategies and measurements are not sufficient by themselves, and they need to be managed to improve energy performance and comfort at the same time. For this reason, monitored or simulated energy demands can be categorized, the problems identified and decreased by taking appropriate measures. Commissioning services are valuable to maintain the optimum use of resources since installation errors and malfunctions can be a major contributor to decreased energy performance (Cali et al. 2016). If the energy demand of a building is much higher than a similar building, building retrofit may be necessary. The most common energy retrofit measures are changing the elements of the building envelope by implementing thermal insulation or shading, decreasing thermal bridges and unwanted air changes, design for natural ventilation, and using more suitable and energy-efficient appliances. Furthermore, rebates and financing with low credit rates can be possible with energy utility and bank contracts.

Since most of the energy consumption occurs during the occupancy phase of a building and the action of users play a significant role, automation and control of mechanical and electrical-electronic systems are developed. For instance, Building Energy Management Systems (BEMS) are

automated or computerized to control energy-related building services while increasing user comfort. These systems identify their users, learn their comfort preferences, and offer appropriate solutions. They can also be connected to the user via the cloud, utility services via wireless connections, and thus make real-time performance evaluation possible (Shaikh et al. 2014 provide a comprehensive review of intelligent control systems).

BEMS have been in use since the 1980s and can be integrated within the building. Because communications, information, and automation are constantly evolving with the advances in technology, BEMS generally consists of four main components. The first component consists of sensors and actuators such as temperature, humidity, CO₂, and light. All of the data from sources and sensors are encrypted or decrypted for communication with the main processing unit in the second component. The third component is the main processing unit, where all logic and calculations are performed on the data. It hosts databases and web services, and provides output to user units via programmed algorithms. The fourth component is the machine-human interface and provides user control and access to communication protocols. Its reports generally show the status of sensors to the user via mobile or web applications. The management depends on the aim of the manager and can be done in real-time, hourly, daily, or through adjustments when a situation occurs.

Decreasing Energy Costs

Energy consumption usually is a significant part of the operational budget of a building. Besides decreasing the amount of energy consumed by the building, the physical and legal infrastructure and how energy is supplied to the building are the main elements of decreasing energy costs.

Since increasing energy demands on the electricity grid create a strain in many cities, one solution is for grids to be more flexible and robust to deal with special needs. Therefore, decreasing energy demand on the side of the consumer is desired by the electricity suppliers, and is named

energy demand management (or demand side management). Delaying the peak load of the building or making the energy requirements of the building more homogeneous throughout the days and seasons are valuable strategies used in energy demand management. For this reason, measures to decrease electricity costs for off-peak load times are necessary and widespread measures include time of use tariffs or critical peak pricing. They can be implemented by either programming the functions of the building so that they do not overlap or make use of energy storage technologies (for a review of energy demand management measures, see Palensky and Dietrich 2011).

Developing strategies for generating their electricity from onsite or renewable resources and incorporating them into the management plan of the building can be a necessity for a building energy manager. While the intermittent nature of renewable energy resources makes their real-time utilization a challenge; adding energy storage capabilities to the production system can cause the costs to increase to nearly twice, therefore grid connection can be a good choice if available. Yet the addition of renewable energy resources put a strain on the grid mainly because of their intermittent nature, so feeding unconsumed energy to the grid cannot always be possible. Tronchin et al. (2018) analyze and discuss issues and models relevant to making decisions to integrate demand side management and energy storage into buildings.

Some governments and authorities have policies to increase the amount of renewable energy in the electricity sector, or other political priorities like greenhouse gas emission management, clean air pacts, and UN Sustainable Development Goals, thus they subsidize or otherwise encourage the utilization of local decentralized renewable energy production. The availability of renewable energy alternatives can be more expensive, yet they can be subsidized or their price can be made compatible by making use of dynamic pricing or making contacts with sustainable energy resource suppliers. Other procurement options also have to be investigated to decrease energy costs. Especially in large-scale projects, building

energy management has to be taken into account with sustainability management. Moreover, buildings can be integrated with infrastructure and transportation systems in smart buildings and cities. The cooperation between prosumers (both producers and consumers), producers, and operators is a must for the sustainability of the energy grid.

Social Engagement

There is a wide gap between predicted and actual building energy performance and occupant behavior, therefore research on changing occupant behavior is emerging. There can be major variances in the energy consumption of similar units in the same or similar building blocks due to the number of occupants, their schedules of being inside the unit, their need for fresh air, difference in lifestyles, socioeconomic circumstances, and the difference between thermal, acoustical, and visual preferences. All of these elements can be classified under occupant behavior, in addition to the interaction of occupants with building elements and systems including unplugging electrical devices; setting thermostats for heating, cooling, and hot water; operating windows and blinds; and closing devices when the users are not present. The energy-saving potential of occupant behavior is estimated in the range of 10%–25% for residential buildings and 5%–30% for commercial buildings (Zhang et al. 2018). Martinaitis et al. (2015) propose that the desire to control is the main cause of this gap.

Societies are becoming information societies, therefore both the utilities and the building energy managers collect a number of data, thus they can provide feedback on the consequences of the occupants' life choices, and educate and encourage them to behave more consciously. Governments, local authorities, and various interested stakeholders campaign to increase energy responsible behavior as a way to combat climate change (Scherbaum et al. 2008), since behaving in one pro-environmental way crosses over to other areas, that is various energy-related behaviors of occupants are interlinked. While decreasing

greenhouse gas emissions in people's lifestyles can correspond with responsible building energy use, Littleford et al. (2014) report that settings such as office and home identify different behavioral features. Besides, there are various experimental works in encouraging pro-energy behavior including education, and increasing energy, climate, and social awareness. Psychology-based interventions include giving feedback within the context of information of similar consumers and reframing of energy-related issues. Technical advancements make it easier to behave more energy consciously by having access to more options to less energy-intensive devices and designing or making it easier to schedule events without decreasing comfort.

Summary

Decreasing energy consumption, utility costs, the utilization of energy resources, or carbon footprint are all valid reasons for managing building energy. From a limited point of view, an energy manager starts to work with the commissioning of a building over a certain size. Yet in fact, energy needs to be evaluated during the design phase. From a wider perspective, city authorities, utilities, developers, and other stakeholders are a part of the management process. In this context, determining, monitoring, and evaluating the energy needs of a building, decreasing the demand by optimizing different variables, and reducing the consumption are among the targets of building energy management. Besides, simulations during design, careful detailing, and evaluating resources from a life cycle cost point of view would help to realize this intention. Also, integrated management with building systems, tariff selection, and scheduling of energy demand activities in the agreements with utility companies are important. Moreover, communication with other buildings, infrastructure services, generating their own energy, etc. should also be evaluated.

In order to maximize user comfort, feedback should be provided to users regarding their education, behavior, comfort, energy, place

attachment, and climate consciousness. One user's capability to decrease the total building energy consumption is limited, whereas a building energy manager can help many users to come together and realize big scale projects, that is, projects bigger than an individual user can. The one to pay for all the costs is usually the owner, therefore split incentives among owners, users, builders, and utilities can decrease resistance to building and living in high energy performing buildings. In addition the physical needs of the users, their psychological needs, and costs are significant in the energy management of a building.

Buildings of the future can be evaluated within the scope of applications that can be realized by using today's state-of-the-art technologies while taking the economy into account. Although many buildings and communities with targets such as zero energy and zero waste have not been successful yet, great progress has been made in the last decades. Perhaps the most ambitious and aggressive goals in the world are decarbonization and net-zero targets for 2050 set by the EU. EU has mostly established an infrastructure that will achieve the goal of building almost zero energy buildings. Even though EU's goals seem ambitious, there are some prototypes, and some of these technologies will probably mature in the near future; therefore, similarly aggressive goals can be set throughout the world within a slightly longer timeframe.

Definition

What is corporate social responsibility (CSR)? Should corporate social responsibility be a business strategy? Both of the preceding questions are deceptively simple! This is evident from the quagmire arising from the ways academics and practitioners present and practice CSR. The result is a gamut of definitions contending for relevance and acceptability in the literature. CSR is a social construction that is multi-perspectival and multi-dimensional. Reviews of CSR definitions (see, e.g., Carroll 1999; Dahlsrud 2008) present CSR as a multidimensional overlapping construct with crisscrossing interpretations. Each dimension captures the unique way scholars and practitioners conceive CSR. Accordingly, five dimensions of CSR are identified, namely, environmental, social, economic, stakeholder, voluntariness/ethical/discretionary/philanthropic, and legal dimensions.

The environmental dimension, CSR, is defined as an attempt by organizations to show visible concern for the health of the natural environment by ensuring that their operations all through the value chain do not jeopardize ecological sustainability. Further, the social dimension of CSR tries to explain CSR from the prism of the nexus between business and society. Here CSR is seen as a corporate obligation or responsibility to ensure that they contribute to a healthier society through avoiding practices that would negatively impact the society but vigorously undertake actions that promote the good of the society. The economic dimension of CSR makes a case for CSR to be a strategic path to fulfilling the profitability and other goals of a firm. According to its proponents, CSR is justified if it serves as a tool for maximizing the profit aspiration of the firm. Another dimension of CSR is the stakeholders also referred to as stakeholder groups. It portrays CSR as a strategic responsibility of firms to care and interact with its stakeholders within and outside it to maintain supportive collaboration that supports the continued progression of the firm. This means that CSR would be sub-defined further according to the individual interests of the various stakeholders of the firm. For instance, employees who are one of the internal stakeholders of the firm would define a firm's CRS in terms of the staff welfares and job security. CRS is also defined from the voluntariness of the firm to do things not necessarily because of legal obligations, but majorly because they consider it ethical and are willing to it voluntarily even without any selfish interest. The legal dimension introduces the logic of legal responsibilities. Legal responsibility refers to a firm's conduct that is "consistent with expectations of government and law" (Carroll 1991:40).

Introduction

Resolving the Tension in Theory and Practice: The Stakeholder Theory

The origin of corporate social responsibility (CSR) is fluid, which originates from its diverse definitional perspectives. Therefore, it is arguable

that the concept and practice of CSR predates contemporary age. Therefore, the broad themes of CSR are replete in the literature of the Ancient Greek philosophers, the Bible, and the Middle Ages (Cannon 1994; Blowfield and Frynas 2005; Ciulla 1991). Hence, ancient themes on ethics broadly cover topics that proxy CSR. Also, businesses of earlier times engaged in practices that promoted social welfare as a payback gesture to the society or interest groups or even as a means for promoting their interests. Contemporary CSR has “corporate philanthropy” as its ancestry! Back then, “companies recognised the need to build schools and health centres, for example, as a means of securing the social license to operate” (Newell 2008:1065). From this perspective, CSR could mean an act of “enlightened self-interest,” which is acting morally not just for the sole benefit of others but nearly for self-interest. The modern CSR is traced to the 1800s or the era of the industrial revolution (Carroll 2008) but gained prominence from the 1950s. Yet, despite over half a century of theorization, many tensions persist, resisting a consensus understanding of CSR. Given the continuing widening perspectives and perceptions about CSR, the tensions regarding the epistemology and ontology of CSR continues to get tighter and, at the same time, grow more robust. It is an enigma, “a fad that may never fade.”

Despite the growing debate on CSR, the stakeholder’s theory provides a richer theoretical framework to explain CSR’s nature, scope, and motives. In the 1960s, the Stanford Research Institute first employed the term stakeholder in a corporate context “as a generalisation of the terms stockholder or shareholder” (Modvar and Manuel-Navarrete, 2016). The CSR was defined narrowly as all the groups that influence the survival of an organization (Bonnafeous-Boucher and Rendtorff 2016). Freeman (1984), and other scholars later expanded the meaning to reflect anyone or organization whose action can affect the attainment of organizational objectives or who can be affected by the same. In this sense, a firm’s stakeholder is context and time dependent. Mitchell et al. (1997) identify a firm’s stakeholder in terms of the extent such person is use the

criterion of being useful to the organization. Accordingly, a stakeholder to an organization at any point is one/organisation whose action and perhaps inaction matter to the organization.

One important lesson from the stakeholder’s theory is the apparent fact that organizations are no longer isolated institutions. Instead, they represent a system of negotiated interests where one’s negotiation depends largely on the level of influence one can assert on the attainment of the one’s objectives. Therefore, from the organisation’s point of view, CSR serves as a veritable thread for knitting the diverse interest groups and galvanise them to achieve the objectives of the organization. Thus, CSR serves as a system for assuaging the opposing expectations of the diverse interest groups as a means to ensure sustainable engagements. From this perspective, CSR is increasingly being constructed as a strategy for creating an appropriate environment for organizations to achieve their goals. To this extent, any CSR that does not contribute directly or indirectly, currently, or in the future to the attainment of the goals of organizations may be unattractive to the organization. This forms the point of departure for the business case for CSR.

Should CSR Be a Business Strategy?

The stakeholder theory indicates that for a business to operate in an environment conducive for profit-making and survival, there are parties internal and external to the organizations whose interests must be protected or taken into cognizance. In other words, for continued business operation, businesses must factor in the interest of these parties; otherwise, profit-making or survival can always be distorted. These groups include but are not limited to employees, suppliers, shareholders, host communities, customers, government, pressure groups and activists, competition, and environmental factors such as technology, politics, economy, and sociocultural systems, among many others. Whenever any of these groups’ interests seem to have been neglected either in the short run or long run, covertly or overtly, that constituency would trigger a response that could disrupt the chaos that would generate an unimaginable effect on the organization. This

phenomenon is called the *butterfly effect*, which is discussed elsewhere in this volume. A typical case is the death of George Floyd in the USA and COVID-19. Both events were not directly linked to any business organizations in the strict sense of it. However, they escalated on a global scale with unimaginable implications. They suddenly became CSR issues. In the case of George Floyd, organizations and individuals started donating to promote the general good of the black race, not just in the USA but all over the world. Organizations used the opening to shop and trade for reputational capital. In the same manner, the impact of COVID-19 on the human race globally created a window for organizations, nations and politicians to engage in CSR activities that position them as caring, socially responsible citizens and brands. Arguably, such actions, even if they are decimal are expected to create goodwill and attract rewards from stakeholders.

Indeed, increasing evidence is mounting, suggesting that most organizational publics believe that organizations are not sincere with their CSR claims. There seems to be a wide margin between what organizations claim in their CSR reporting and what the publics expect from them (Nkamnebe, 2021). There seems to be increasing suspicion of corporate hypocrisy when it comes to CSR performance of some organizations. Nkamnebe and Igwenazo (2019) report that some multinational oil companies in Nigeria's Niger Delta are typical of this act. Again, the CSR crisis that erupted in Ogoni land that resulted in the killing of environmental activists is replete in the literature. Alluding to this, Wan-Jan (2006:180) opines that "the dissonance between what the public expects firms to do and what they think the firms are doing is worrying." Scholars (see, e.g., Wan-Jan 2006) are enacting the business perspective to CSR by arguing that organizations should leverage CSR to regain public goodwill for sustainability. In addition, Lewis (2003) and Porter (2003) argue that CSR is potential sources of competitive advantage.

Carroll and Shabana (2010) synthesize the business case for CSR and argue that even from inception, CSR initiatives have the underlying supposition that CSR will provide some form of benefit to the firm at some point. Accordingly,

CSR evolved from ethically camouflaged to visible economic/financial beneficial engagement of firms.

Carroll and Shabana (2010:91-92) pose the following questions that address the issue of business case for CSR:

can a firm do well by being good? Is there a return on investment to CSR? What are the bottom-line benefits of socially responsible corporate performance? Is corporate social performance (CSP) positively related to corporate financial performance (CFP)? (For business practitioners), a 'business case' is 'a pitch for investment in a project or initiative that promises to yield a suitably significant return to justify the expenditure'. That is, can companies perform better financially by addressing both their core business operations and their responsibilities to the broader society? (Kurucz et al. 2008.

At the surface, it may look like the quest for a business sense of CSR is solely on the shoulders of the leaders of firms and their shareholders. However, the truth is that the various dimensions of CSR are so intricately related that, in the final analysis, everyone benefits from it. Everyone in one way or the other becomes stakeholder! The entrepreneurs are interested in ensuring that they receive a reward for their risk-taking through the continued stream of profit. The government wants a fair cut by way of tax to boost its financial position and execute their social contract with the citizenry. Employees are interested in ensuring their welfare during their active work lives and retirement. Suppliers would want to deal with sustainable businesses that guarantee continued good business relations and even consumers want firms that produce the right product for them that at the same time maintains a healthy and sustainable environment. Perhaps, it is in this context that Edward Freeman, in his stakeholder model argue for businesses to create value to its stakeholders as a strategic choice for survival (Freeman, 1984). On the other hand, Milton Friedman argues that the only justified social responsibility of a business is to increase and protect the expectation of the shareholders – shareholder model of business (Friedman 1962, 1970). Considering the interconnectedness of contemporary society and the increasing emphasis on sustainability, a broadened approach to CSR makes huge sense. Accordingly, businesses

cannot operate in isolation for long. At the same time, society cannot survive if businesses are overburdened to the extent of lacking the motivation to operate and encourage the emergence of new ones. Thus, as has been suggested, “Friedman must also accept a view of business as embedded in social interdependency, which serves as the logical and moral foundation for corporate social responsibility” (Ferrero et al. 2012).

Increasing scholarly and practice-based approaches have been documented to showcase the increasing importance and recognition of the business case for CSR. For instance, Carroll and Shabana (2010:92) report the following:

1. The business case for CSR has been broken down into four different categories by Simon Zadek. Zadek has argued that companies pursue CSR strategies to (1) defend their reputations (pain alleviation), (2) justify benefits over costs (the “traditional” business case), (3) integrate with their broader strategies (the “strategic” business case), and (4) learn, innovate, and manage risk (New Economy Business case) (Zadek 2000).
2. Kurucz et al. (2008, pp. 85–92) also have set out four general types of a business case for CSR, which overlap with Zadek’s. They maintain that there are four different groupings of the business case based on the *focus* of the approach, the *topics* addressed, and the *underlying assumptions* about how value is created and defined. Their four approaches include (1) cost and risk reduction; (2) gaining competitive advantage; (3) developing reputation and legitimacy; and (4) seeking win-win outcomes through synergistic value creation.
3. Other widely accepted approaches to the business case include focusing on the empirical research linking CSR with CSP and identifying benefits to different stakeholder groups that directly or indirectly benefit companies’ bottom lines.
4. Also, the socially conscious investment movement, sometimes called “ethical investing,” is often built on the belief that there exists a strong correlation between social performance and financial performance.

Key Issues

Today’s interconnected and interdependent systems, including economic systems with increasing enlightenment of stakeholders, pose a serious challenge to organizations in diverse ways. First, with the increasing awareness of the import of sustainable development goals (SDGs), the number of businesses’ stakeholders is increasing, and businesses must respond to the sustainability responsibility from consumers as a strategic option to survive. This rising consciousness of becoming stakeholders and increasing democratisation of consumption present a new frontier of growth, which organizations should leverage for better performance. Second, society is critically evaluating the social performance of all organizations including the governments toward building a sustainable society. The sustainable development goals (SDGs) are increasingly becoming a new metrics for society to measure the performance of businesses and government. As a result, businesses, in particular, must devise better ways to frame their social responsibilities and communicate them in order to benefit maximally from it.

Amid these issues, businesses are increasingly becoming under pressure to ensure that their investments reflect on their financial performance. This, in a way, makes enormous sense as businesses must make more profit to meet the expectations of the mounting stakeholders. Besides, they need to adapt, innovate, and survive in an environment that is increasingly being shaped by rapid technological innovations and recently being disrupted by new forces like COVID-19. How can businesses survive in turbulent environment and not offend the conflicting expectations of multiple stakeholders?

Future Directions

Corporate hypocrisy in CSR management has become crucial in businesses’ future growth strategies. Corporate hypocrisy in the context of CSR claims arises when there is inconsistency in a firm’s CSR claims and public performance of such claims. With increasing awareness and

expectation of CSR, and firms' attempt to present socially responsible corporate citizen imagery, managing CSR communications will continue to present a serious strategic challenge to firms. Arguably, a poorly managed CSR communications have far-reaching potentially damaging reactions from the known and unknown stakeholders of the firm. Hafenbrädlä and Waeger (2021) collaborate this assertion and document research evidence suggesting the likely low consequence due to responses from consumers (Baskentli et al. 2019), investors, and other stakeholders (Jones et al. 2014). They went on to assert that any claim of CSR engagement may be perceived by stakeholders as image laundering propaganda and mere empty talk (Aras and Crowther 2008); and if such promises becomes too mouth-watering it may be seen as hypocritical (Jordan et al. 2017). In other words, crafting and communicating CSR must be done with expertly, particularly in contexts where companies' intentions cannot be easily inferred from their actions. One very popular way of framing CSR activities involves invoking the business case for CSR (Bird and Waters 1989). The business case for CSR revolves around the claim that it pays to be socially responsible and that there is a "win-win" situation in which profits and morality are aligned. For instance, Larry Fink, the CEO of BlackRock (the world's largest asset management company), wrote the following in a recent letter to S&P 500 CEOs: "To prosper over time, every company must not only deliver financial performance, but also show how it makes a positive contribution to society" (Fink 2017). To illustrate just how often the business case frame is used to pragmatically motivate CSR activities, a recent study found that 58% of Fortune 100 companies have framed their diversity strategies in exclusively pragmatic terms (23% have used both moral and pragmatic frames and 4% have used an exclusively moral frame (Nurmohamed et al. 2018).

Introduction

Amfori Business Social Compliance Initiative (amfori BSCI) was founded by the Foreign Trade Association (FTA, today: amfori) in 2003. It is a retail and business initiative designed to

review and improve social standards along global value chains of consumer goods (Eggert, 2015, 140). In order to meet its objectives, amfori offers companies a code of conduct (amfori BSCI Code of Conduct) and several tools to manage the social and environmental performance of supply chains. The code covers eleven principles of decent work and covers the following issues:

1. The Rights of Freedom of Association and Collective Bargaining
2. Fair remuneration
3. Occupational health and safety
4. Special protection for young workers
5. No bonded labor
6. Ethical business behavior
7. No discrimination
8. Decent working hours
9. No child labor
10. No precarious employment
11. Protection of the environment

Companies who wish to join the program are supposed to protect workers' rights and implement the amfori BSCI Code of Conduct. Furthermore, they need to inform workers about their rights and responsibilities and offer them a whistleblowing hotline. Additionally, they are supposed to influence other associate partners to adapt the amfori BSCI Code of Conduct in order to cause a cascade effect.

The History

The history of amfori BSCI dates back to the year 1977, when several companies founded the Foreign Trade Association (FTA), an organization that incorporates the foreign trade interests of European salesmen, trademarks, and importing wholesalers to international institutions.

In the face of environmental and social challenges, FTA constantly evolved its scope. In 2003, they founded the Business Social Compliance Initiative (BSCI) as a public-private partnership (PPP) with the German Society for Technical Cooperation (GTZ) (GIZ, 2003). With BSCI, they were aiming to offer enterprises a system to develop social compliance along their supply chains.

This efficient system was honored by the DNWE (Deutsches Netzwerk Wirtschaftsethik) with the Corporate Ethics Award in 2008 (DNWE 2019).

In view of the success of BSCI, a new governance structure was adopted in 2011 and sustainability was included in the core business. Since 2014, the Business Environmental Performance Initiative (BEPI) has been part of the offering in order to support companies that are aiming to improve environmental performance in their supply chains. In 2017, FTA turned 40. Alongside this anniversary, FTA introduced its new strategy: vision 2030. The idea of vision 2030 is that open trade might cause and enhance environmental and social progress. Parallel to its new vision, FTA introduced its new name in 2018: amfori.

Definition: Mission, Objectives, and Focus Areas

Amfori BSCI is a holistic system for reviewing and enhancing minimum requirements of decent work. It includes an auditing system and appropriate training and training measures. Amfori BSCI focuses on three topics:

- Auditing of production sites and farms to verify the degree of implementation of the amfori BSCI Code of Conduct
- Training of participants and their suppliers in order to improve the understanding and implementation of the amfori BSCI Code of Conduct
- Continuous dialogue with stakeholders (governments, trade unions, etc.) to improve the political, economic, and cultural situation with the overall goal of sustainable improvement of working conditions

(Kontaktgruppe BSCI Schweiz, 2016)

The initiative sees itself as a facilitator that enables participating companies and their suppliers to meet challenges related to social standards within international value chains (Eggert, 2015, 140).

The amfori BSCI code of conduct introduced in 2014 comprises 11 principles (mentioned

above) and is based on the conventions of the International Labor Organization (ILO), the Universal Declaration of Human Rights, the UN Declaration on the Rights of the Child and the Convention on the Elimination of All Forms of Discrimination against women (CEDWA), the UN Global Compact, and the OECD guidelines (Kontaktgruppe BSCI Schweiz, 2016). Further, the amfori BSCI code of conduct addresses the UN Sustainable Development Goals 1, 2, 3, 4, 5, 8, 10, 16, and 17 (Amfori, 2019).

By joining the amfori BSCI, companies commit themselves to involving their suppliers in the amfori BSCI process and are constantly checked for their progress. The suppliers of the BSCI participants undertake to comply with the BSCI Code of Conduct and are audited accordingly. In addition, the companies are supported with training in further development.

The verification and confirmation of compliance with the Code of Conduct is carried out by independent companies accredited by Social Accountability International (SAI) and selected by the BSCI, with local nongovernmental organizations and employee representatives.

The amfori BSCI Code of Conduct with its 11 principles is translated into 13 interconnected "Performance Areas" (PAs):

- "Social Management System and Cascade Effect
- Workers Involvement and Protection
- The Rights of Freedom of Association and Collective Bargaining
- No Discrimination
- Fair Remuneration
- Decent Working Hours
- Occupational Health and Safety (OHS)
- No Child Labour
- Special Protection for Young Workers
- No Precarious Employment
- No Bonded Labour
- Protection of the Environment
- Ethical Business Behaviour" (Amfori, 2019)

The Amfori BSCI "full audits" evaluates all thirteen "Performance Areas." Audits take place every two years, which constitutes the "amfori

BSCI audit cycle." "Amfori BSCI follow-up audits" are conducted in between these intervals and have to take place within twelve months from the previous audit. They treat those performance areas that need improvement.

The overall result of an amfori BSCI audit shows the company's status quo of implementation. The results of the audits can range from A to E. For "A" (Outstanding), 86-100 % of the criteria must be met, whereas the result "E" (Unacceptable) only meets 0-29 % of the criteria. If companies achieve the result A or B under the "Full Audit," the certification is valid for two years. In the case of C-E results, the auditee has to offer a remediation plan within 60 days of the audit date. Additionally, a follow-up must be carried out no later than 12 months after the full audit (Amfori BSCI Handbuch, 2019, 48).

The results of the audits are generated automatically by the amfori BSCI IT system. Even the auditor is not informed about the final rating until they submit the audit results to the amfori BSCI platform. Therefore, in the closing meeting of the audit the auditor focuses on all the findings (good as well as bad ones) and is not able to name a rating.

There are three types of audits: audits which are fully announced, semiannounced, or fully unannounced. Semiannounced audits are audits where the audited company is aware that an audit will be conducted soon, though it is not informed about the exact day of the year.

Depending on the size of the operation to be audited, an auditing process can take 1.5-5 days (Amfori BSCI Handbuch, 2018, 53).

Today, amfori BSCI covers all industries and can be used in all countries (Kontaktgruppe BSCI Schweiz, 2016).

Structure of Governance

The following organization chart shows the overall structure of amfori, which hosts the Amfori BSCI Code of Conduct (picture, <https://www.amfori.org/content/our-governance>) (Fig. 1)

Amfori is directed by a "General Assembly" that is composed of all types of amfori members:

Our governance structure

B

Business Compliance Initiatives, Fig. 1 Governance structure

ordinary, associate, and affiliate. According to their turnover, “ordinary members” have the right to vote. The “board of directors” manages amfori. Its members represent salesmen, importing wholesalers, trademarks, and companies from different geographic areas and industries, and therefore reflect the diversity of amfori itself.

The board of directors is supported by a number of councils and committees, which offer help and advice regarding strategic issues and upcoming trends. Networks provide amfori with additional information from a local perspective, and project groups support amfori with their expertise on specific matters.

Major Accomplishments and Critics

Amfori BSCI has more than 15 years of experience in improving social performance within supply chains. It is active in over 130 countries. More than 2,000 companies have joined the initiative, and there are more than 54,000 producers listed on the amfori BSCI platform (Amfori BSCI, 2018).

On the occasion of the tenth anniversary, Jörg. S. Hofstetter and Marc Müller of the University of St. Gallen published a study on the

history and successes of amfori BSCI. It turned out that India has become the country with the highest number of compliant producers in recent years (Hofstetter & Mueller, 2013, 14; 18).

According to the study, the main procurement markets are China, India, Bangladesh, Turkey, and Vietnam. At the end of 2011, they account for nearly 89 % of all audit-methodology-consistent producers (Hofstetter & Mueller, 2013, 14).

Within the first year, after BSCI was founded, 14 out of 15 audits applied to the clothing and textile industry; within the following years, the focus extended to other goods such as leather, shoes, jewelry, and electronics (Hofstetter, 2009, 25).

The share of producers (of all product groups) that accomplish a “good” rating is increasing. About 60 % of all nonfood factories reach compliance at the end of 2011 (Hofstetter & Mueller, 2013, 15).

Irrespective of positive headlines, Amfori BSCI has repeatedly been criticized – especially from NGOs – for the fact that it is not an independent multistakeholder initiative in which companies, trade unions, and NGOs are equal members. Another point of criticism is the voluntary participation. The requirements remain nonbinding for the industry, and the audits are commissioned

within the industry. The view from outside, for example, by external nongovernmental organizations, is not taken into account. In addition, amfori BSCI is criticized for its few requirements regarding the wage level and the lack of disclosure of the audit results to the public. Furthermore, amfori BSCI has been criticized for the fact that not the entire supply chain has to be considered, but only direct suppliers. Subsuppliers might commit serious violations of labor rights, but that has no influence on the outcome of the amfori BSCI certification process. Another point of criticism relates to the common practice of prior notification of audit controls, which offers suppliers the opportunity to hide grievances. Besides, it is criticized that the amfori BSCI has hardly any means for sanctions in place (except the exclusion of companies from the initiative) whenever a company violates the BSCI requirements (Mußmann, 2017). Various critical articles have been published over the years.

Especially the Clean Clothes Campaign (CCC) had a critical eye on the amfori BSCI. They criticized the work of the initiative against the background of the factory collapse in Rana Plaza, Bangladesh. A few months before the disaster, TÜV Rheinland audited the production site of Phantom Apparel Ltd. The German certification company did not criticize the documents on building safety and did not adequately examine some other shortcomings. TÜV Rheinland was commissioned by a member of the Business Social Compliance Initiative. According to CCC, the BSCI certificate primarily serves the image of companies but is of little use to workers in global production and supply chains, as the example of Rana Plaza shows (Kampagne für saubere Kleidung, 2017).

Summary

Amfori BSCI is a holistic system for reviewing and enhancing minimum requirements of decent work. Besides being an auditing system, it also comprises appropriate training and training measures. The initiative looks back on more than

15 years of experience in improving social performances within supply chains. Despite much criticism, amfori BSCI is still a famous option when it comes to social auditing (Amfori BSCI, 2018).

[Ecosystem approach](#); [Ecosystems](#)

Summary

Business ecosystems are loosely coupled, dynamically coevolving associations of firms that compete and cooperate interactively to achieve complementarity and innovation resulting in mutually shared value creation. Business ecosystems have developed as firms have experienced increasing levels of competition, change, and globalization in their environments requiring them to seek more efficient models to

organize and innovate. The business as ecosystem metaphor has developed over the last several decades to explain interdependent networks of firms that represent a different form of organization distinct from hierarchies, supply chains, or free markets. The business ecosystem concept has been developed overtime through the work of several scholars including Cusumano, Moore, Iansiti and Levien, and Adner. Studies of business ecosystems as instances of complex systems have analyzed them in terms of their distinctive characteristics including: emergent behavior, value sharing, coevolution, and complementarity.

Defining Business Ecosystems

Business ecosystems are loosely coupled, dynamically coevolving associations of firms that compete and cooperate interactively to achieve complementarity and innovation resulting in mutually shared value creation. Since scholars have tended to focus their attention on the specific characteristics of business ecosystems, however, there is still no widely accepted overall definition of a business ecosystem (Bogers et al. 2019).

Based upon an extensive literature review of the field Bogers, Sims and West have proposed a definition of a business ecosystems as “an interdependent network of self-interested actors jointly creating value” (Bogers et al. 2019, p. 2). Adner identifies two distinct approaches in the conceptualization of an ecosystem: that which focuses on the “ecosystem-as-structure” (activity centric – “the structure of the independent activities that underly a value contribution”) compared with that of the “ecosystem-as-affiliation” (an actor-centric approach) (Adner 2017).

The impact of platform-based business models (Kenney and Zysman 2016) and strategies based upon open innovation (Vanhaverbeke and Cloudt 2006) for both competition and value creation have resulted in great attention being shown to the business ecosystems concept by both scholars and practitioners of management starting from the early 2000s (Adner 2017; Bogers et al. 2019; Greer et al. 2017).

Jacobides, Cennamo, and Gawer have identified three streams in the business ecosystem literature: (1) business ecosystems, (2) innovation ecosystems, and (3) platform ecosystems (Jacobides et al. 2018, p. 2257). The business ecosystem approach focuses on firms as actors in a community of interaction (Teece 2007), the innovation ecosystem orientation looks at the way in which firms collaborate in order to provide “customer-facing solutions” (Adner 2006, p. 98), while the platform ecosystem approach is concerned primarily with technological interdependencies between sponsor and complementors (Ceccagnoli et al. 2012). Rapid change in many business environments calls for more flexibility and speed in the development and application of new and diverse skills. The increasing pressure of globalization and competition have highlighted inefficiencies in traditional organizations of production (Ghisi and Martinelli 2006, p. 462) and prompted firms to seek more flexible methods to organize and manage risks and opportunities (Fuller et al. 2019, p. 2).

The business as ecosystem metaphor represents a move away from the atomistic view of firms as isolated competitors in markets (Granovetter 1985; Gulati et al. 2000) and the limitations it imposes for understanding the competitive dynamics of commitment and flexibility in interfirm relationships (Gulati 1998, p. 295).

Development of the Business Ecosystems Concept

The defining characteristics of ecosystem-based business becomes clear when compared with that which prevailed previously. Previously, the key to maintaining a competitive advantage was contingent upon developing and maintaining excellent resources within the corporate organization. The primary concern of corporations was to exploit economies of scale in production and sales strategies. For this, firms emphasized the importance of excellence in their human resources, technologies, and made it a policy to create these resources internally.

In accordance, firms pursued policies of vertical integration whereby they acquired and absorbed smaller firms with competitive (excellent) resources. The result of this – as is clear from the representative case of the “Detroit Model” of the automobile industry – was the development of large, powerful corporate groups. This corporate consolidation was based upon a strategy of “make or buy” where the choice was to either buyout a supplier or control it as part of the corporate supply chain. Thus, by controlling more resources than their competitors, firms were able to leverage economies of scale while preventing imitation and thereby secure greater returns on their investments. This model was described by Chandler as the classical model of twentieth century US industry (Chandler 2009).

Cusumano has defined the dominators of the Detroit model as “Product Platformers” – firms which have created a supply chain in order to produce their own products – and distinguishes them from “Industry Platformers” (Cusumano 2012). While product platformers gain by delegating the production of important integral parts of their products to external firms, industry platformers are able to leverage strong network effects. Industry platformers see themselves as partners in naturally occurring ecosystems rather than as controllers of supply chains. As seen in the case of Microsoft and Apple, firms based on business networks do not attempt to internalize all the resources and capabilities critical to their businesses. Industry platformers create ecosystems based upon massive networks of multiple partner firms using the technological infrastructure afforded by advances in information technology. The development of the business ecosystem concept can be traced through the work of three influential theorists in the field: Moore, Iansiti and Levien, and Adner.

Moore: The Ecology of Business

Moore is credited as having introduced the term “business ecosystem” into the management field (Elkington 1998, p. 44; Muegge 2013, p. 11) by proposing an ecological approach to management. By applying an ecosystem metaphor to business networks, Moore emphasized an

assumed rule of the jungle wherein ecosystems were led by a firm as the dominant species which maintains control by defining strategic direction over the other members and wherein member firms gain profit by maintaining “bargaining power” over each other (Moore 1993, p. 81).

Moore states that the distinction between ecological and business ecosystems is that a: “biological ecosystem is a community of organisms, interacting with one another, plus the environment in which they live and with which they also interact, while business ecosystem is an economic community supported by foundation of interacting organizations and individuals – the organisms of the business world” (Moore 1993, pp. 26–27). Business, unlike biological ecosystems are based on voluntary contractual relationships motivated by mutual gain.

This early application of the ecosystem concept emphasized the cyclical nature of group formation as new innovations were introduced and commercialized and either collapsed as they were made obsolete or renewed by the adoption of the next generation of technology (Moore 1996, p. 47). Moore later described the business ecosystem as the result of a process of mutual alignment among “customers, suppliers, competitors, and other stakeholders, who coevolve their capabilities and roles” (Moore 1996).

Iansiti and Levien: The Relationships of Ecosystems

Following Moore, Iansiti and Levien also adapted language from ecological ecosystems in order to further explain the dynamics of business organization and explain the possibilities of interfirm activity in terms of distributing risk and cost in order to gain synergies and achieve innovation. Iansiti and Levine contend that the most critical issue for firms today is how to best leverage critical resources which they neither own nor control (Iansiti and Levien 2004a). Iansiti and Levine provide a theoretical construct by which the concept of a business ecosystem can be operationalized and its management assessed.

According to Iansiti and Levine, in business, as in biological ecosystems, many actors are connected to form a network. These connections

are complex and highly interactive and the soundness of individuals depends on the soundness of the entire ecosystem because: “like an individual species in a biological ecosystem, each member of a business ecosystem ultimately shares the fate of the network as a whole, regardless of that member’s apparent strength” (Iansiti and Levien 2004b, p. 69). Iansiti and Levine have identified this interdependent network effect as a defining characteristic of business ecosystems.

Iansiti and Levien identify productivity, robustness, and niche creation as the dimensions by which to measure strength in a business ecosystem. In order to create and maintain a business ecosystem, it is necessary to create value within it and assure that value is shared among its constituents (Iansiti and Levien 2004a, p. 91). In order to create value, ecosystems must innovate – this requires that there are opportunities for niche players to innovate within the ecosystem and that there is sufficient benefit from innovation to warrant ongoing investment in new value creating capabilities.

The key to this for Iansiti and Levien is the “operating leverage” provided by the ecosystem. Operating leverage is the strategy of the keystone firm by which it provides a series of assets that can be “easily scaled and shared by a broad network of business partners” within the ecosystem by its members. These assets can be physical, intellectual, or financial but must be managed in such a way as to ensure that the value derived from their leverage rapidly exceeds their costs as the number of ecosystem members increases – thus creating a surplus of value which can be shared (Iansiti and Levien 2004a, p. 92).

One of Iansiti and Levien’s key contributions has been to elucidate the strategic roles played by firms within business ecosystems. Iansiti and Levien define five roles – keystones, niche players, dominators, and hub landlords – each of which represents a different strategy to leverage the value of a business ecosystem.

Iansiti and Levine redefine Cusumano’s industry platformers as keystone companies – firms that act as network hubs in order to benefit both themselves and the members of their ecosystems by providing technological or service-based

platforms that can be leveraged in their own strategies. keystones serve to manage and regulate a large number of companies in the network to build a stable and predictable platform. By doing so, the numerous and loosely connected ecosystem partners retain their interdependence and grow. Niche players leverage the platform of the keystone by developing unique, differentiating capabilities which are critical for the strength and innovation of the ecosystem as a whole. Dominators are often large firms that extract value from ecosystems to the disadvantage of other firms thus undermining the health, versatility, and potential growth of the ecosystem on the long term. Hub landlords do not attempt to dominate the ecosystem but extract value in the form of “rent” from the use of resources vital to the platform while creating little or no value in return.

Iansiti and Levine maintain that a business ecosystem is not therefore simply a corporate group, but that its participants are loosely connected with each other for the common purpose of survival and productivity. This coordinated yet highly distributed form of network structure is markedly different to the structure of previous corporate groups. The networking of business ecosystems: “requires only interoperability and extensibility based on satisfying just sufficient protocols for interaction and leveraging” (Anggraeni et al. 2007, p. 8).

Adner: The Structure of Business Ecosystems

Adner identifies two approaches in the conceptualization of ecosystems: affiliation and structure (Adner 2017, pp. 39–40). Adner classifies the approaches of Moore (1993, 1996) and Iansiti and Levien (2004a) as *ecosystems-as-affiliation* wherein ecosystems are defined as “communities of associated actors defined by their networks and platform affiliations” as opposed to his own *ecosystem-as-structure* approach wherein ecosystems are defined as an “alignment structure of the multilateral set of partners that need to interact in order for a focal value proposition to materialize” (Adner 2017, pp. 39–42).

In contrast to the ecosystems-as-affiliation approach takes the members of an ecosystem as its starting point, the ecosystems-as-structure

starts with the value proposition, the activities that are required to realize it and from then goes on to examine the actors involved and their ability to perform the actions required of them (Adner 2017, p. 44).

Adner defines a business ecosystem from this “ecosystem as structure” approach as “the ecosystem is defined by the alignment structure of the multilateral set of partners that need to interact in order for a focal value proposition to materialize” (Adner 2017, p. 42).

By focussing on the creation of a value proposition and its realization as the objective of a business ecosystem, Adner is able to define the structural requirements of a business ecosystem in terms of four basic elements: (1) Activities: what must be done in order for the value proposition to be realized, (2) Actors: who is necessary to perform these activities, (3) Positions: the interaction between actors whereby activity is ordered and flows, and (4) Links: the transfers between actors of material, information, finances, and or influence which may or may not include the focal firm (Adner 2017, p. 43). Business ecosystems cannot be equated with supply or value chains. Unlike supply chains that are defined by a well determined path that is reducible to bilateral partnerships (Adner 2017, p. 52), interfirm relationships within ecosystems are characterized by their multiparty interdependence and mutable nature.

Adner explores the relationship between the concepts of business ecosystems and business models. Adner identifies the difference between a business model and a business ecosystem when he observes that an individual firm may adopt an ecosystem strategy as its own business model, but its own particular business model will not become an ecosystem. Ecosystem strategy is defined by Adner as the “way in which a focal firm approaches the alignment of partners and secures its role in a competitive ecosystem” (Adner 2017, p. 47). For Adner: “The successful ecosystem is composed of multiple firms acting in concert – an ecosystem strategy can be thought of as one that takes partner firms’ business model to be as critical to address as the focal firm’s” (Adner 2017, p. 51).

Adner’s formulation differs from that of Moore and Iansiti and Levien in that the latter defines

ecosystem boundaries in terms of formal partnerships, whereas the former recognizes the influence of actors outside partner relationships and presumes change.

A further key contribution of Adner's structural approach therefore is that it "explicitly extends the strategic view to include activities and actors over which the focal organization may have no control, and with whom they have no direct contact" (Adner 2017, p. 44). The participation (or non-participation) of firms and individuals in business ecosystems therefore becomes purposeful and ecosystem border identification becomes an issue. Adner's structural approach to ecosystems therefore encompasses the dimension of external and potential relationships and sets the stage for the consideration of trust and business ecosystems.

Characteristics of the Business Ecosystem Concept

Despite the emergence of different approaches to and conceptualizations of the concept of the business ecosystem, there are several characteristics central to most interpretations. Fuller, Jacobides and Reeves have identified seven characteristics of what they term the "ecosystem perspective" as including: (1) dynamism which assumes the flexibility of coevolutionary relationships comprising the ecosystem, (2) collaboration as a result of complementarity between the development of innovative capabilities, (3) governance which is based upon influence rather than direct and formal control, (4) emphasis on sharing value created in order to enable and promote innovation in other firms, (5) openness to the possibility of serendipitous change as a result of emergent behavior of the ecosystem as a complex system, (6) multilateral interdependencies between firms in multiple networks, and (7) porous boundaries whereby firms strategic interests extend beyond their own immediate boundaries or supply chains (Fuller et al. 2019, pp. 2–3).

Lengnick-Hall and Wolff have identified three distinct and contrasting logics within recent strategy research – these being: "resource-based

views, hypercompetitive/high-velocity studies, and ecosystem/chaos theory research" (Lengnick-Hall and Wolff 1999, p. 1110). Lengnick-Hall and Wolff locate the business ecosystem approach within the third logic of "complexity" because of its use of a systems thinking approach to strategy. For Lengnick-Hall and Wolff, the business ecosystem's approach to strategy can be characterized by the assumption that: "strategic success is a function of a firm's talent for thriving in dynamic nonlinear systems that rely on network feedback and emergent relationships. Effective strategies therefore require a blend of competition and cooperation. Paradoxical relationships, positive and negative feedback, and dynamic tension embedded between various actors and processes, as well as between a firm and its context, are fundamental elements of complexity logic. Strategy is reconceptualized to mean the design of processes that create attractors, facilitate desirable flows, foster synergy, integrate subsystems, capitalize on community, and simultaneously eliminate errors and reduce entropy. Traditional notions of competitive advantage do not carry much weight in complexity logic" (Lengnick-Hall and Wolff 1999, p. 1114).

Lengnick-Hall and Wolff identify six premises that define the complexity logic that drives the business ecosystem approach: (1) the success of firms within the ecosystem is dependent upon that of the overall health of the ecosystem and therefore of the health of each of its component sub-systems, (2) progress moves in a nonlinear manner in complex systems and the accommodation of unplanned and unpredicted events and development is important, (3) the ecosystem is shaped by its attractors – the values and visions upon which it is based and by which the behavior of member firms is influenced and shaped, (4) change is constant and ongoing and strategies must be renewed as relationships and contexts shift, (5) the multiple cross interdependencies among ecosystem member firms gives rise to self-organizing transformation based on emergent behavior, and (6) the boundaries of the ecosystem are established and maintained by the commonality of values and the effect of attractors rather than the force of procedure

based guides to behavior (Lengnick-Hall and Wolff 1999, pp. 1114–1115).

Underlying these characterizations are two key pragmatic themes for the management of business ecosystems: value creation and governance.

Value Creation in Business Ecosystems

Adner has proposed that the objective of a business ecosystem is the creation of “value that no single firm could have created alone” (Adner 2006, p. 98). Adner is referring to the value created out of the network effects of the business ecosystem itself. Muegge has elaborated on this by explaining that: “by operating a business within a networked ecosystem of interdependent and co-dependent businesses with partially aligned incentives, a technology entrepreneur can achieve more, learn faster, and reach farther than otherwise possible, while sharing some of the risks and costs with others” (Muegge 2013, p. 6). Membership in a business ecosystem can allow firms to leverage the assets of other members – in terms of both their currently leverageable resources and the capabilities to generate and contribute new, nongeneric resources within the ecosystem. The potential of the ecosystem to create value in this manner is the product of complementarity.

Jacobides, Cennamo, and Gawer have noted that: “as we define them, then, ecosystems are groups of firms that must deal with either unique or supermodular complementarities that are nongeneric, requiring the creation of a specific structure of relationships and alignment to create value” (Jacobides et al. 2018, p. 2257). Healthy ecosystems must attract members. The potential of an ecosystem to create value for its members is its greatest enticement. For its members, the value creating potential of an ecosystem is located in three sources: the externalities of the network, the diffusion of innovation within the ecosystem, and open versus closed innovation (Shapiro and Varian 1998, p. 204).

The role of ecosystem members in terms of both their capability to operate as a business and

their strategy for interaction with the other members of the ecosystem are important factors in determining the value creation potential of the business ecosystem as a whole. Bogers, Sims, and West have explained this as: “the value creation for an ecosystem depends on the contributions of the actors. On the one hand, all ecosystem members have a stake in its success. On the other hand, the nature of the relationship *between* the actors – particularly whether their respective goals are competing or complementary – will influence how (or how well) they will work together to achieve that success” (Bogers et al. 2019, p. 2). As discussed above, however, despite the obvious importance of creating and sharing surplus value in an ecosystem, and the many studies of ecosystems which assume value creation within ecosystems, few to date have attempted to actually analyze and measure the value creation within actual instances of business ecosystems (Bogers et al. 2019, p. 6).

Governance of Business Ecosystems

Interactions between firms as business activity requires some form of coordination. As discussed above, business ecosystems contrast sharply with the hierarchies of vertically integrated firms, closely managed supply chains and with the free associations between firms in open market situations. Moore (2006) argued that business ecosystems are a distinct organizational form – a mode of organizing economic production that differs from markets and the organizational hierarchies of firms. The coordination of business ecosystems is incompatible with the binding contractual arrangements of hierarchies, the static interfirm agreements of supply chains, and the periodic transactions between firms in the open market.

The effective governance of business ecosystems is currently seen as a new competitive advantage in business strategies that require managing networks of firms in order to achieve the ongoing provision of transformative business solutions. Jacobides, Cennamo, and Gawer characterize business ecosystems upon the basis of the way

by which they resolve what they term the “coordination challenge” (Jacobides et al. 2018, p. 2260). The challenge being how to effectively coordinate a: “set of actors with varying degrees of multilateral, nongeneric complementarities that are not fully hierarchically controlled” (Jacobides et al. 2018, p. 2257).

Business ecosystems constitute an intermediate form of organization, one shaped by mutual interdependence without contractual obligation. The coordination of business ecosystems is better characterized as governance through influence rather than management by control. In order to respond to the “coordination challenge,” the governance of business ecosystems must fulfill several functions. Governance must (1) encompass the constituents of business ecosystems as they interact through three shifting roles of cooperation, competition, and coopetition (Bogers et al. 2019, pp. 9–10), (2) allow organizational modularity to develop, function, and change within the ecosystem (Jacobides et al. 2018, p. 2255), (3) function as a network of “specialised and complementary opportunity niches – both known and yet to be discovered” (Muegge 2013, p. 11), while allowing (4) the “local interactions, emergence and feedback” (Reeves et al. 2016, p. 47) which ensure the adaptability and sustainability of the business ecosystems. Governance, for business ecosystems becomes a matter of coordination for mutual survival and benefit.

Synonyms

Corporate social responsibility; Doing good; Ethical conduct; Ethics

Definition

Business ethics can be viewed as consisting of three main areas of endeavor. These are: (1) a consideration of the ethics of business, that is, an examination of the application of broadly accepted ethical norms to business; (2) an field of academic

research and teaching in which normative and critical examinations of business practices are subjected to ethical critiques and examinations of justifications; and (3) an applied endeavor by businesses to alter behavior to comply with broader societal ethics including law as a minimum standard (Buchholz, 1989) and more broadly, corporate social responsibility (Sheehy, 2015).

The common ethical approaches of teleology, deontology, virtue ethics, and pragmatism are used in all three types of business ethics endeavors (MacDonald, 2015; Ferrell et al., 2015; Fontrodona et al., 2013; Whetstone, 2001; Bradburn, 2001; Richardson, 1995). Teleologically, the ultimate end that justifies for-profit business is a public good. Deontologically, business ethics identifies problems with exploitative business practices and argues that these practices are not permissible on deontological grounds (Buchholz, 1989). Virtue ethics thinkers focus on the actions and decision-making of executives and consider how generally accepted virtues might be useful in guiding or judging decisions and actions in a business context (Solomon, 2005). Pragmatism provides an approach to business ethics which rejects an ideal, true knowledge about right and wrong. It seeks instead to provide a balance between parties and their legitimate interests, allowing needs to be met within contemporary social systems of production, distribution, and consumption while acknowledging limitations and problems with those systems (Peterson, 2021; Visser, 2019; Richardson, 1995).

Introduction

Business ethics can be described as a “new, very old concept.” From one perspective, ethical thinking has its origins in the writings and thoughts of the great philosophers such as Socrates, Plato, Kant, and Confucius. These philosophical traditions are much concerned with thinking about what is moral, right, or wrong and also how we make informed judgments and defend our moral position. With respect to business ethics, Aristotle wrote that an exchange of things of equal value was

just and ethical (“Aristotle” *Nicomachean Ethics*, Bk V: 5).

As new ideas and institutions such as capital markets developed, however, further thinking about business and business ethics was required. Thinkers such as John Locke and Adam Smith provided new justifications for, as well as limitations on, how the economic system ought to work and what was appropriate for business (DeGeorge, 1992). Others, most famously, Karl Marx, developed systematic attacks on the underlying premises of capitalism and the capitalist system (Jackson, 1996). Business is an institution in much of the world today and business ethics, therefore, involves a study of institutions (Velasquez, 2012; Crane & Matten, 2010; Nickels et al., 2008). As such, business ethics includes the study of business institutions, situations, activities, and decisions where issues of right and wrong are addressed (Crane & Matten, 2010) and extends beyond immediate business concerns to include considerations of social justice (Khalidah et al., 2018) and the environment.

Bradburn (2001) states that business ethics is not just about being moral, but it is also concerned with adopting an ethical approach that may have strategic advantage of the business. In this sense, business ethics becomes a type of business strategy and “doing good” becomes a means of achieving profit or a means of delivering effective services in a way that enhances the common good. Common themes include social scientists’ positive research on the impact of ethics on businesses, arguments on the agency of the corporate organization, and normative debate on right and wrong in the conduct of business.

The focus of most contemporary business ethics is on the actions or omissions of organizations dedicated to for-profit activities. That is, the business ethics discussion is about the ethics of for-profit enterprises, their actions, and underlying values. This entry adopts that focus.

Business Ethics Defined and Clarified

The term “Business Ethics” is used in a variety of ways to denominate an area of thought about

right and wrong where ethics and business interact. Scholars define business ethics as organizational principles, values, and norms that may originate from individuals, organizational policies or from the legal system, social institutions, and broader civil society that guide individual and group behavior in the context of business operations and transactions (Ferrell et al., 2015; Carroll et al., 2018; MacDonald, 2015).

Business ethics is the study of those practices in organizations and is a quest to determine whether or not these practices are morally acceptable. Solomon (1992) suggests that the values of business life and the life outside of business are rarely far apart. Allison (1998) argued that ethics is fundamental to business conduct and that a moral relationship based on trust lies at the foundation of all agreements between people and two organizations. Business ethics as an academic discipline is, therefore, a specific but limited discipline that considers moral and ethical decision making in economic organizations such as business corporations. The scholarly endeavor analyzes rules, standards, codes, or principles that provide guidelines for morally right behavior in specific business situations and the actual decision-making and conduct of businesses. As a practice, business ethics implements these rules, standards, and codes through decision-making and conduct.

Three Areas of Business Ethics

There are three broad areas where business ethics is considered. These are considerations of: (1) the ethics of business as a social activity – an examination of the application of broadly accepted ethical norms to business, (2) the academic field of business ethics which examines business practices in terms of ethical critiques and justifications, and (3) business ethics as an applied endeavor – an applied endeavor by businesses to alter behavior to comply with broader societal ethics including corporate social

responsibility (Carroll et al., 2018) and a professional practice.

Ethics of Business as a Social Activity

The discussion of business as a social activity and business ethics in that context examines and questions what is right or considered ethical conduct in society generally and whether and how this broader social morality coincides with or is ignored by business. This line of inquiry has developed from thinkers like Locke and Marx, as mentioned above, to the deeper and broader societal responses to specific matters, in evidence such as environmental harms and consumer product liability (DeGeorge, 1992). This area is often examined as corporate social responsibility which is defined as “international soft law norms seeking to ameliorate and mitigate the social harms of and to promote public good by industrial organizations” (Sheehy, 2015). It is often described as the extent to which organizations meet and exceed societal expectations regarding a firm’s economic, legal, ethics, and philanthropic responsibilities (Prakash Sethi, 1975; Carroll, 1979). Ness (1992) makes an important observation with regards to CSR activities. Just as organizations that meet minimum legal requirements of society cannot be considered as irresponsible, meeting such obligations not means that an organization is necessarily responsible.

Along with this wider, secular criticism of business behavior, a long, significant line of religious thinking has been focused on business behavior, also using ethical language (Mele, 2015; Ruel, 2020; Kamarudin, 2020). Basic principles, such as the prohibitions on lying and deceiving found in most religious traditions as well as advocating justice such as supporting safe and fair working conditions, are part of this tradition. The Roman Catholic Church in the late nineteenth century advocated for a just or living wage under Pope Leo XIII. That pope was the first pontiff to address the problems of industrialization directly in his encyclical *Rerum Novarum*, which literally means “Of New Things.” The encyclical, while accepting a right to private

property and capital, also addressed other aspects including the recognition of workers’ rights, the unacceptability of child labor, and the need for a living wage (Catholic Church, 1940). *Rerum Novarum* is often advanced as the foundation of modern Catholic social teaching and a foundation of an era of more broadly socially progressive thought.

Various scandals, environmental disasters, and corruption, particularly where there is government involvement, have been a catalyst for public interest in business practices and public protest as well. This public discussion drew academic attention and provided a segue into the academic study of business ethics. In sum, understanding business ethics as a critical examination of a social activity “business” has been useful in drawing attention to harms inflicted by the social institution and prompted organized social response.

Academic Field of Business Ethics

Just as ethics is the systematic study of morality, the mores, or right and wrong of any given society, the academic field of business ethics seeks to expose the principles that make acts just or unjust, to uncover unjust rules and support just rules, and to ensure consistency and coherence among the rules (DeGeorge, 1992). It examines the conduct of business as a social activity including a focus on the accepted norms or practice within the business community. Rather than appealing to universal norms, it connects with and reflects upon the specific socio-historical context of behavior in the business community.

Within the academy, business ethics is a branch of applied ethics with a focus on ethics of for profit, not for-profit organizations, and public sector organizations and the people within the organizations. It examines all actions, conditions, and dilemmas in business and provides frameworks for analysis, challenge, and resolution or justification of those actions, conditions, and dilemmas, predominately using the frameworks of utilitarian, deontological and virtue ethics, and often advocating a combination of two or more (Buchholz, 1989; Velasquez, 2012; Ferrell et al., 2015; MacDonald, 2015).

In conducting their research, business ethicists pursue three distinct research agendas: (1) one a normative agenda examining how ethics should work, (2) an empirical group who sought to describe what was actually occurring in businesses and how ethics approaches could be incorporated as part of business structures, processes, and the production of goods and services, and (3) what aspects of ethics should be taught within traditional business education in addition to how it should be taught. While the first business ethic academic agenda was often found in association with philosophy departments and theological seminaries, the second and third were generally found in the management schools, where scholars and practitioners having expertise in society and business relationships and management training were employed (Sheehy, 2012, 2015; Segon & Booth, 2014).

In terms of the first research agenda, greater attention to business practices emerged following numerous corporate scandals in the 1970s, such as the Hooker chemical disaster in the Niagara, NY, suburb of Love Canal; the substandard Ford Pinto car and resulting deaths, and the range of corporate takeovers of the 1980s from the junk bond M&As, to the notorious collapses of firms like Enron and World Com of the 2000s (DeGeorge, 1999; Beauchamp & Bowie, 1993; Weiss, 1994). These examples focused the attention of not only scholars, but vocal critics such as Ralph Nader, who drew the attention of the general public causing them to consider the behavior and decisions of senior executives and the cultures of organizations that allowed significant harm to individuals and society in general in order to generate profits.

This wider social dialogue led to legislative action. Steinmann and Olbricht (1996) note that Federal US legislation had a critical impact on the policies, operations, and behavior of American corporations. It led to the development of ethics and compliance-based approaches, with codes of conduct, ethics training, and an attempt to develop ethical corporate cultures. In particular, it did so via criminal sentencing. The 1991 US Federal Sentencing Guidelines started by addressing both the personal responsibility of corporate officials and the punishment of the organization for

criminal conduct. The 1994 US Sentencing Commission further identified the development of an effective program to prevent and detect violations of the law as a mitigating factor in the determination of the level of fines imposed on an organization. Further, Steinmann and Olbricht (1996) and Izraeli and Schwartz (1998) argued that the guidelines had a significant impact on the establishment or enhancement of corporate ethics programs in the USA and that the impact was directly attributable to the relationship between the size of the fine and the existence of the compliance or ethics program within the organization.

Among the first scholars to research corporate ethics and organizational approaches was the late Dr. W. Michael Hoffman, the founder of Bentley's Center for Business Ethics. Hoffman focused on corporate structures and managerial approaches including leadership, communication, training, and development and management of employee performance as means by which to develop appropriate corporate cultures. Hoffman (cited in Drummond & Bain, 1994) made the point that it is generally the failure of the corporate control systems that provides the opportunity for unethical actions of its employees. In this view, an organization can enhance the ethical behavior of its workforce by improving corporate culture, that is, by recognizing the influence of significant others and the context in which decisions are made that may provide the opportunity for employees to engage in unethical behavior (Ford & Richardson, 1994; Vidaver-Cohen, 1998; White & Lam, 2000; Adams et al., 2001).

Harvard Professor, Lynn Sharp Paine, elaborated and refined Hoffman's approaches identifying two types of ethical systems: (i) a compliance approach that used a normative foundation for prescribing ethical corporate behavior and (ii) an integrity approach that parallels virtue ethics as a means of guiding and enhancing culture and corporate behavior (Sharp Paine, 1994). This typology has in turn been developed further by numerous researchers; however, a feature of all of these approaches is the use of codes of conduct and codes of ethics as a form of organizational policy and related procedure. Beyond Hoffman and Sharp Paine's typology, Segon (2007), using

the organizational design theories of Mintzberg (1981), noted that the compliance and integrity approaches parallel only two of multiple corporate structures prevalent in the business world. Hence, Segon argued that a new approach was required, which while using the same components of leadership, policy training, etc., included the development of ethical culture. This development, he argued, needed structural variants, including multiple codes of conduct and ethics that aligned to each organizational structure and purpose, consistent with Mintzberg's (1981) hypothesis of "fit."

Business ethics in academic work includes training, often in professional programs as found in business schools. Hoffman's contribution to business ethics was not limited to organizational research but extended to education with the development of one of the first business ethics concentrations in an MBA program – a project that he developed at Bentley College in Massachusetts in the 1980s. Hoffman argued that there was a clear need for ethics inclusion in business education in order to balance the singular profit maxim of most of the substantive business topics such as marketing, accounting, strategy. Buchholz (1989) and Crane (2004) explicated the critical issue, namely, that business students are taught all the substantive areas of business including theories of management, but are not exposed to and taught about the implications of business thinking and its potential in terms of poor or unacceptable business ethics (Trevino & Nelson, 2006).

Current approaches to management development and training, most notably the Emotional Social Competency Inventory or ESCI, contain little if any appeal to ethics and morality (Segon & Booth, 2014). Concerningly, from a business ethics perspective is Caruso and Salovey's view that "the emotionally intelligent manager's moral perspective is, we hope, well developed" (2004, p. 171). This assumption illustrates the ongoing concerns about how to ensure the moral dimension is developed in business leaders. It is a concern, for as Orme and Ashton (2003) and Segon et al. (2021) argue, ethics is a foundation competency and that individuals cannot be expected to follow ethical rules unless they actually understand them. Segon and Booth (2014) suggest

that ethics needs to be developed using an input-based competency approach addressing the conceptual, behavior, and attitudinal knowledge required to be a superior performing manager (Boyatzis, 1982; Hellriegel et al., 2008; Salovey & Mayer, 1997; Pedler et al., 2013; Quinn et al., 2015). Unfortunately, as one might surmise from statements like Caruso and Salovey's, the inclusion of ethics within business training continues to be haphazard with numerous studies identifying inconsistent approaches as to whether ethics should be taught as a stand-alone unit or embedded throughout other content (Alsop, 2006; Evans & Robertson, 2003; Hartman & Hartman, 2005).

Business ethics has been a burgeoning area of scholarship. The year 1980 saw the first professional conference and academic society, the Society for Business Ethics, established. Its members were primarily philosophers drawn into management division of the Academy of Management. Two years later, independently of the Academy of Management's decision, the leading journal in the area, the *Journal of Business Ethics* was founded in 1982. The Academy of Management's initiative launched the journal, *Business Ethics Quarterly* in 1991 – a journal that has gone on to considerable success. A network of business ethics societies has followed around the globe, including the Society for Business Ethics in the USA founded in 1979/1980, European Business Ethics Network founded in 1987 in Belgium, and the Australian Association of Professional and Applied Ethics in 1992. Business ethics journals of various types and with different locations and focuses have sprung up around the world.

Business Ethics as an Applied Endeavour and Professional Practice

Business ethics is turned into an actionable organizational policy framework through the ideas of corporate social responsibility. Corporate social responsibility includes ethics. Indeed, it is impossible to consider a corporation as being socially responsible if it does not account for its ethics (Sheehy, 2012). As noted, it has developed into a form of global soft law (Sheehy, 2015). Corporate

ethics as a compliance matter deals with the hard law obligations imposed by public regulators.

The professional practice of business ethics has had rather mixed results. Where business ethics has been part of an organizational strategy, it is often relegated to a marketing team or public relations department. These teams and departments that use business ethics are part of a branding exercise or a differentiation strategy. Business ethics may well have little to do with how the organization makes decisions or operates. It is usually considered part of a Corporate Social Responsibility strategy ending up in “greenwash,” “blue wash” or whatever colored cause the business seeks to align itself with (Greer & Bruno, 1996).

Levels of Business Ethics

Both DeGeorge (1992) and MacDonald (2015) suggest that business ethics can be analyzed at a number of levels: at an individual with considerations of personal responsibility, at an organizational or firm level, at an industry level, and at a national and finally an international level. We discuss each in turn. The focus of the first level is on personal responsibility, personal development, and ethical decision making. MacDonald (2015) notes that a range of influences will affect how we approach an issue. Ultimately, people must personally and individually make a decision and take responsibility for that decision at least in the realm of one’s own conscience.

The second level concerns the internal structures and processes of an organization with attention to fairness and procedure, and related principles such as transparency, as well as problems arising from a lack of attention to these matters. As agents of a firm, people are required to make decisions on behalf of or in the interests of organizations rather than being guided by self-interest. This fact leads to an important question: If a manager makes a decision for an organization on the basis of one’s understanding of the best interests of the organization and not for personal reasons, who is to be held responsible for the outcome where a negative outcome results: the organization, the manager, or both?

An example of this organizational ethical risk can be illustrated by a single focus on output. An instruction to “get it done whatever it takes” can be read as an invitation to ignore proper protocols. While the production may indeed increase, without sufficient regard to process the output may well end up with serious ethical problems. There may be increased worker injury, damaged relationships with suppliers, or products or services that are harmful or poorly accepted by customers.

The industry level focuses on the examination of the norms of an industry, such as the extractive industry or chemical or financial industry. The problems faced by participants in these industries cannot be resolved by individual firms on their own. Rather, the firms need to coordinate themselves to address and solve industry-wide issues arising from such ethically challenging concerns as pollution, destruction of the natural habit, or predatory behavior. The solutions to such problems are often developed through multi-stakeholder initiatives and promulgated through industry codes, as for example, Forestry Stewardship Council’s code (Sheehy, 2019).

The fourth level is the national. The nation-state has a variety of tools available to address ethical issues. Indeed, it is an expectation of the citizenry that the government will step in to deal with powerful industrial actors to address matters that private citizens lack the power to address on their own or even collectively. There are numerous questions which arise at the national level and in particular, the obligations of firms and organizations, including multinational corporations, to that society. Concepts such as the social contract and the license to operate need to be considered.

The fifth level is the international level. As this level, multiple actors are pursuing multiple different and often conflicting objectives. For example, multinational corporations, various governments, and international actors will be pursuing different objectives, some of which will be in conflict in the following scenario. A multinational corporation may be planning to move operations from one jurisdiction to another jurisdiction to avoid stricter environmental regulations and regulation of unsafe working conditions. This move is expected to reduce operating costs of the multinational

corporation. At the same time, governments in both jurisdictions will have different agendas. The move may bring much needed employment and revenue to the weaker jurisdiction. Such a move, however, may damage the community where it is currently operating and providing employment to a significant part of the population. Finally, international organizations such as the International Labour Organisation or an environmentally focused NGO may focus on the respective concerns of their organizations to influence the multinational corporate actor. There are obviously an host of ethical questions as to whether the multinational should be moving.

The sixth level, the global level, like the national level has severe ethical challenges. These challenges arise not only from the multinational corporation and disparate agendas of many actors but extend as the global challenges are not resolvable in one part of the globe without affecting all of the globe, regardless of their location. Matters such as global warming, a by-product of industrial activity, cannot be resolved by multinational corporations and some governments acting in concert. Rather, in matters that touch global concerns, the need for business ethics, analysis and debate, comes to the fore.

International Business Ethics

Both De George and MacDonald note the international context, with its diversity of cultural norms, laws, and standards as presenting significant ethical dilemmas. The most significant ethical theory for addressing this aspect of business is relativism. Relativism acknowledges that national cultures play a critical role in determining moral values and standards of ethical behavior (Becker & Fritzsche, 1987; Hofstede, 1980; Langlois & Schlegelmilch, 1990; Vitell et al., 1993). Ethical relativism claims that conflicting views held by different national cultures and societies can be right and further that morality and ethical principles or judgments are relative to the norms of one's culture. Accordingly, whether an action is right or wrong depends on the moral norms of the

society and the time in which it was done (Velasquez et al., 2015; La Follete, 2014; Buchholz (1989).

If one accepts ethical relativism, then one must also accept that there can be no common framework for resolving or reaching agreement on moral disputes or ethical matters among members of different societies. Hinman (2012) suggests relativism is only feasible when cultures do not have to interact with one another. As the global COVID pandemic has illustrated, our societies are inextricably linked and the challenges of coordinated responses stemming from relativism cannot be ignored. For managers and leaders working in a cross-cultural or international context, dilemmas occur continuously. They will be confronted with practices and approaches that may be considered unethical in their home country yet part of normal practice or *modus operandi* in another. The ethical challenge these leaders face is how to deal with these dilemmas. Perhaps the most confronting for those from Western cultures are those dilemmas that involve requests or offers of additional payments, facilitation, gifts, or unusual favors, in other words forms of bribery and corruption. Those from other cultures are often just as uncomfortable with the requests and offers; however, their long exposure and experience with these cultural issues helps them deal with the requests and offers more easily.

These offers and requests, in ethical terms, "bribery and corruption," are the two main issues for international business. There are multiple definitions/perceptions of meanings of corruption, including "the misuse of authority for personal, sub-unit, and/or organizational gain" (Ashforth & Anand, 2003, p. 2). Transparency International (2000, p. 1) defines corruption in a way that fits both the public and private context: "the misuse of public power for private benefit." The term bribery is more often described as the action of giving or receiving a financial or other advantage in connection with the "improper performance" of a duty by a party in a position of trust, or execution of a function that is expected to be performed impartially or in good faith.

Practices that are deemed “bribery and corruption” are seen as unethical in one country; however, they can be seen as consistent with the business norms of another, and thus, it can be argued that they are ethical. Donaldson and Dunfee (1999) describe this as the “when in Rome” approach – an approach drawn from the Bible. The saying is “when in Rome, do as the Roman’s do,” meaning follow the local norms. With respect to bribery and corruption, many managers use the “when in Rome” approach as a justification for engaging in such practices. Accepting this approach, however, creates the potential paradox of an organization accepting in one country what it prohibits in another. This simultaneous acceptance and prohibition appears to be unfair – a double set of rules applying to managers and other employees depending on where they are. It is made more complex by the fact that many transactions are multinational and it is unclear where the exact location of the transaction can be said to occur. Donaldson and Dunfee (1999) argue that the “when in Rome strategy is a mistake because it exposes the company (and its brand names) to corruption and public affairs disasters, and because it misses the opportunity to find the glue that cements moral and cooperative strategy.”

Perhaps the most significant initiative in combatting global corruption is the United States’ Foreign Corrupt Practices Act of 1977 – a piece of legislation that sought to outlaw the practice of bribing a foreign government official in order to secure contracts or gain market advantage. A similar initiative was published by the OECD as a convention on bribery and corruption. In 1996, it required all members of the OECD to develop and ratify anticorruption legislation. This initiative has been implemented. For example, the United Kingdom introduced one of the most stringent and far-reaching pieces of legislation in 2010 known as the simply as the UK Bribery Act, which applied to both public and private sector organizations. Australia has its own Foreign Corruption Provisions: Section 11.5(1) and 70.2(1) of the Criminal Code Act 1995. Similar legislation has indeed been introduced by many countries around the world

with anticorruption bodies springing up to enforce the provisions.

Summary

Business ethics is a long-standing concern. It has a wide variety of focal points – from labor, to environment, to product liability. There are three main approaches: an examination of business as a social activity, an academic discipline, and an applied endeavor. It includes impacts at all levels from the individual to the global. A major challenge arises in the context of international business and relativism.

Definition

Business in the Community (BITC) is one of the Prince's Charities and the UK's largest business-led membership organizations committed to promote corporate responsibility practices (Idowu 2013).

This organization undertakes to work with businesses to drive change, thus responding effectively to growing concerns such as community engagement, unemployment, diversity, and circular economy. In concrete terms, BITC seeks to trigger a change in the perception of their members and to fuel their commitment to the well-being of the society. To this end, it provides businesses with expert advice and specialist resources, and it is committed to shed light on best practices by convening, sharing learning, and publicly recognizing valuable performance across its influential network (BITC 2017).

Concerning its institutional status, BITC constitutes a public benefit entity complying with FRS 102, and it emerges as a company limited by guarantee and a registered charity in England, Wales, and Scotland (BITC 2018). At a

supranational level, BITC acts as the convener of the CSR360 Global Partner Network, the largest global network of not-for-profit organizations championing Responsible Business, assuming that the terms “Responsible Business” and “Corporate Responsibility” are deemed as tantamount to Corporate Social Responsibility (CSR) (Idowu 2013). Currently, this Network is made up of 133 independent organizations from 67 countries, and it reaches over 6,000 companies around the world (BITC 2017).

Brief History

In the 1970s, although the enactment of some socially responsible regulatory provisions (Idowu and Towler 2004), governance crisis erupted due to some critical issues such as the 1973 oil crisis, political weakness, and economic stagnation. Both conservative and labor governments were ill-equipped to address the high rates of inflation, public debt, and unemployment and, more broadly, to deal with a changeable commercial and political environment. Consequently, it occurred the reduction of state responsibility for social provision and, facing growing community riots, the government acknowledged its societal governance deficits, laying the foundations for a higher and higher private sector involvement (Vertigans 2015).

As evidence thereof, following a government conference where a group of US business leaders involved in the urban regeneration of Baltimore and Detroit in the 1970s shared their experiences with their British counterparts, and on the back of the Toxteth and Brixton race riots in 1981, Business in the Community (BITC) was established as a token of a collaboration between government and business (Moon and Richardson 1985; Grayson 2007; Idowu 2013). Actually, it should be kept in mind that BITC built on the work of pre-existing groups such as the Action Resource Centre and the Community of St Helens Trust (Grayson 2007).

Basically, BITC history might be split up in at least three major phases (Grayson 2007). During Phase I in the 1980s, it predominantly championed business support for local enterprise

agencies as a way of business helping to regenerate local economies depressed by corporate closures. With this regard, a major activity was to encourage small business development and reskilling (Grayson 2007).

During Phase II, dating back to the 1990s, BITC was involved in promoting a wider agenda of corporate community involvement. Specifically, the focus was on helping businesses better organize their involvement (Grayson 2007). Lastly, Phase III has seen BITC embrace corporate responsibility, also known as “responsible business.” The business driver has shifted more to competitive advantage for individual companies and the pressures of sustainability as a business challenge. Throughout, BITC has encouraged companies to get involved individually and to work together through collective business action (Grayson 2007).

Almost 40 years after forming, BITC still acts as a connecting bridge between business and society, devised to address those organizations, which are willing to “act responsibly and to invest in building a better and more healthy society” by anchoring the development of their businesses to the prosperity of society (BITC 2018).

BITC Vision

BITC is intended to support businesses to realize where they can best contribute, and it provides them with the appropriate guidance, tools, and insights to make this happen.

Basically, BITC membership is grounded in the idea that the success of business and society are mutually dependent. Therefore, if every individual business strives to be the best it can be in all areas as a responsible business, there will be a positive multiplier effect, which would be amplified by the cooperation and shared learnings among all the businesses. This would translate into enhancing the society, the economy, and the environment, and it would contribute to build the UK’s growth in the long term.

After all, being a responsible business is useful for each business since it can produce bottom-line business benefits in terms of staff recruitment and retention, brand value and reputation, managing risk in supply chain, driving innovation and

productivity, and opening up new markets. Moreover, it can lead to the adoption of new business models, such as those ones related to sharing and circular economy (BITC & Doughty Centre for Corporate Responsibility 2011; Department for Business Innovation and Skills 2014).

In the light of the above, once joined the BITC network, each member is expected to do two things: on the one hand, to embark on a “journey” of continuous improvement that may lead to social, environmental, and economic sustainability and to measure and to account for its CSR performance and, on the other hand, to collaborate with other businesses and relevant actors involved (such as local community leaders, charities, voluntary groups, schools, and public sector organizations) and to invest in building a better society, thus transforming communities via transforming each business (BITC 2018).

BITC Mission

At a mission-level, BITC undertakes to help businesses make progress with reference to four different key areas:

1. People: helping business build better workforces
2. Environment: helping business create a sustainable economy
3. Place: helping build healthy communities
4. Impact: helping business measure their impact (BITC 2018)

Within the “People” key area, it is possible to distinguish different fields of interventions.

Concerning the employment one, the Employment Team aims to make work more accessible and sustainable for people who face barriers to employment. Specifically, BITC is committed to make jobs more accessible through campaigns and advice resources granted to its members; to make jobs more sustainable through the development work around good work for all; to support disadvantaged individuals through the so-called Ready for Work Programme; to address tricky issues spread out in any workplace, such as gender equality or the support to a

multigenerational workforce; as well as to overcome workplace barriers associated with race diversity. Concerning well-being area of intervention, BITC is intended to endorse a holistic approach aimed at ensuring the employee well-being in relation to both physical and mental health. With reference to the education area of intervention, BITC helps businesses of all sizes support local schools, with a view of fostering young people – particularly those facing social disadvantage – to develop the skills they will need for work.

Likewise, BITC aims to guide businesses in developing their partnerships with schools.

Concerning “Environment” key area, BITC is expected to inspire and enable smart growth of any business, starting from the assumption that restoring a healthy environment is indispensable if any business hopes for achieving long-term financial success. Concretely, BITC works with businesses to reduce risk and improve the health of water, soil, and biodiversity within their supply chain.

In parallel, BITC “Circular Economy Taskforce” is called to raise awareness and inspire action to bring circular economy to life through knowledge-sharing and networking events (via the so-called Circular Office initiative) and by building up programs of practical collaboration, action, and innovation. A sector-focused work is also being developed with the UK government, with a view of designing policy frameworks and support tools to boost circular economy opportunities nationally.

With this regard, findings of a consultation with “Circular Economy Taskforce” members published in May 2018 call on business, government, academia, and other stakeholders to work together and bring the circular economy to life, since this approach could result in a 3% boost to resource productivity and generate £10bn GVA and 200,000 jobs by 2030 (BITC 2018).

Concerning the third key area named “Place,” BITC is intended to help bridge the gap between businesses and the communities. This entails supporting businesses in building healthy local communities. With this in view, employee volunteering programs might be seen as a powerful lever promoted by BITC to tackle local social issues. In particular, these programs enable

employees to donate time and skills during work hours for the benefits of local communities. For the same purpose, business connectors, as talented employees seconded from either business or the public sector to BITC, might be entrusted to work across a specific city or area, typically less advantaged, in order to develop sustainable partnerships.

Eventually, about the fourth key area “Impact,” BITC is intended to help business measure to what extent it might be framed as responsible, regardless of its size, the sector to which it belongs, and its being listed or unlisted. With this regard, in Financial Year 2017/2018, BITC launched “Responsible Business Tracker,” a new responsible business management and benchmarking tool whose first full cycle will take place in 2019 and that replaced the “Corporate Responsibility Index,” launched by BITC in 2002 (BITC 2018).

As a whole, BITC helps businesses promote leadership and engagement on all levels, as well as it enables to develop skills and expertise required to listen to the local communities’ needs and to meet them. Beyond granting advice resources and measurement and benchmark support tools such as the “Responsible Business Map” (viewed as a useful tool to realize what stage of the responsible business “journey” each business has reached), BITC offers access to a network of employers, and it encourages its members to work together and to share knowledge. By fostering the collaboration between business and community and among the businesses themselves, there are laid down the foundations for co-creating innovative solutions and determining the expected change through direct action.

Facts and Figures Concerning Some Achievements Recorded in 2017/2018

Within “People” key area, with regard to the area of intervention “employment,” 400,000 more older workers have been employed at work in the last 2 years. In parallel, concerning area of intervention “well-being,” in the last year 11,000 people completed the “Mental Health at Work” survey, while, concerning area of intervention

“education,” it turns out that in the last 10 years, 28,800 young people have been reached through the so-called “Business Class” process (BITC 2018). About “Environment” key area, in the last year, more than 80 companies have been working to develop “Circular Office” solutions. With reference to the “Place” key area, it has been found out that in the last year £48.3 M has been leveraged into communities in cash, in-kind donations, and volunteering, including the value of the business connectors themselves (BITC 2018).

Eventually, concerning “Impact” key area, at the end of 2018, BITC began to pilot the Responsible Business Tracker with 82 forerunner member companies from 26 sectors (BITC 2018).

Summary and New Challenges

BITC has been established to support businesses to become more and more responsible. Since its birth, it has been encouraging companies to change the way business activities are traditionally managed, thereby generating benefits for local communities. Nevertheless, nowadays BITC runs the risk of being affected by some upcoming macroeconomic uncertainties. In particular, the UK’s decision to leave the European Union (the so-called Brexit) could push businesses to cut discretionary expenditure, creating a loss of members or a lower BITC programs participation. Membership drop, in turn, may cause the BITC income stream to downsize. As a reaction, BITC should leverage the relationship management, and it should work closely with members to raise their awareness of how much BITC’s activity and campaigns are relevant to deal with societal and environmental needs (BITC 2018).

Synonyms

BITC index; Corporate responsibility index; CR index; CRI

Definition

The Corporate Responsibility (CR) Index is a voluntary benchmarking tool launched in 2002 by UK Business in the Community (BITC). CR Index follows a systematic approach to managing, measuring, and reporting on business responsible business practices and the impacts on society and the environment.

Brief History

According to Business in the Community (BITC), Corporate Social Responsibility (CSR) – also known as Corporate Responsibility (CR) or Corporate Responsibility and Sustainability (CRS) – hints at a voluntary integration of social and environmental concerns into business practice. It's about being a responsible business, thus taking charge of the impacts on society and the environment. Such a CR conception is embedded in the Corporate Responsibility Index (CR Index), considered as the leading benchmark of responsible business in the UK.

In 1996, BITC launched a “Business in the Environment Index” to assess the performance regarding environmental management practices of member companies. In 2002 members requested social issues to be integrated into the index. As a result, BITC established the CR Index in collaboration with over 80 leading UK corporations and with UK-based nonprofit organizations (Spitzeck 2009; El-Masry and Kamal 2013).

As a general rule, participation to CR Index has been open to all the Financial Times Stock Exchange (FTSE) listed companies, Dow Jones Sustainability Index listed companies, and BITC level 1 and 2 and Premier members (BITC 2012). Throughout the CR Index whole period of application, it has been recorded a significantly positive response from corporations, investment fund managers and city analysts, pension funds, insurers, government, and the public. As a matter of fact, over 100 corporations have participated in the CR Index every year from the time of its establishment (El-Masry and Kamal 2013).

Business in the Community Index,

Fig. 1 5-star rating system of CR index performance (BITC 2017)

CR Index urges companies to conceive and deliver business strategies that are consistent with the responsible business framework. To this end, it takes care of conducting a gap analysis, benchmarking against industry peers, and recognizing and communicating achievement of public participants. CR Index stands as an online survey, which prompts companies to report on their social and environmental impacts and to measure to what extent responsible business framework is integrated into their strategy. Companies follow a self-assessment process intended to help them identify both the strengths in their management and CR performance and gaps, where future progress can be made.

Since 2014 CR Index performance moving has been categorized to a 5-star rating system, whose boundaries have been set as depicted in Fig. 1:

Structure of CR Index

The CR Index is organized into four sections:

- Corporate Strategy section
- Integration section
- Management section
- Performance and Impact section

First of all, Corporate Strategy section aims to realize how the business's activities are reflected upon each company, by focusing on the corporate vision and values, the effective governance, and the CR risks and opportunities underlying each business. As a general rule, this CR Index section is meant to reward companies for internalizing CR values in their business strategy. Beyond looking at the effectiveness of company's corporate

governance processes, Corporate Strategy section asks whether there is a system to identify key social and environmental risks and opportunities and whether these are addressed through strategy, policies, and responsibilities held at a senior level. By contrast, companies have to account for leadership and commitment at the highest level, internal reporting to the board and public advocacy of responsible business practice (Hopkins 2005).

Vice versa, Integration section sheds light on how companies organize, manage, and embed corporate responsibility into their operations through strategic decision-making, performance management, training, effective stakeholder engagement, and public reporting. Concretely, the CR Index section under scrutiny is expected to answer the following questions:

- Is the responsible business framework part and parcel of the company culture?
- Is it integrated into the strategic decision-making processes of the company and linked through into internal governance and risk-management systems?

Indeed, as explained by BITC, it is not enough to have a strategy. In fact, any strategy needs to be implemented and embedded throughout the business. This requires internal communication and training employees in finding out the key CR issues for the company and building CR-related performance criteria into appraisal and remuneration systems. Moreover, engaging the stakeholders might be conducive to a more effective CR strategy implementation, as well as embodying social and environmental issues into the strategic decision-making process and raising the transparency degree through external

reporting on CR management practices and impacts may lead to more satisfying end- results.

Subsequently, integration degree is assessed through the Management section, where processes are reviewed for how they manage different stakeholder relationships. Going in depth, Management section assesses whether a company has developed management practices to address materially significant CR issues across four areas:

- Community, that relates to the interface between business and society, positively or negatively affected by a project, product, or investment on a local or global level.
- Environment, that is the world's ecosystems and natural resources that can be directly and indirectly affected by a company's operations, products, and services, to such an extent that being responsible means safeguarding both the systems and resources for future generations.
- Marketplace, that refers to how companies manage business and consumer and supplier relationships, from product development to sourcing, buying, marketing, selling, and promotion of products and services. It also relates to how companies influence the rules of the marketplace in which they operate.
- Workplace, that hints at the creation of a working environment where personal and employment rights are upheld (Hopkins 2005; Hansen and Spitzack 2010).

Overall, Management section is expected to clarify how a company selects and prioritizes key material environmental and social issues; to identify which are the relevant programs around different areas of CR and which are the objectives and targets chosen to steer a continuous improvement; to monitor systems designed to measure, assess, and report on progress; and to keep track of public reporting on key issues, objectives, and targets.

Lastly, Performance and Impact section asks companies to report performance in a range of social and environmental impacts areas. By contrast, participants complete three environmental and three social areas based on the relevance to their business. The environmental impact areas

include one core or mandatory impact, climate change, plus two self-selected area of material significance to the business. For their social impact areas, companies are able to choose between employee engagement and well-being, employee development, equality, diversity and inclusion in the workplace, community investment, international development, or another self-selected impact area. By resorting to focused graphs, CR Index is expected to disclose results and benchmarking information covering the environmental and social impact areas completed by the company. Such information concerns about organizational commitment to managing the issue, the programs in place to drive improvements, and the organizational performance over time.

Given this structure of the CR Index, each company, for its part, is called to answer the questions corresponding to the four sections, which, in turn, are individually weighted, as follows:

- 15% of total score is awarded to the Corporate Strategy section.
- 28% of total score is awarded to the Integration section.
- 23% of total score is awarded to the Management section.
- 33% of total score is awarded to the Performance and Impact section.

Therefore, percentage score achieved by any company results from the weighted sum of all the marks accomplished in each of the abovementioned sections. Each corporation is accountable for signing off its own index findings by CEO or through the board member handling the corporate responsibility to ensure director-level dedication to the reliability of the responses to the survey. In parallel, BITC is committed to strengthen the truthfulness of the Index by deploying checks throughout key stages in the compilation, examination, aggregation, and presentation of information (El-Masry and Kamal 2013).

At the end of the assessment process, the output will be a standard scores report, which

graphically displays the company's management and performance scores across the CR agenda. This will include the benchmark against peer companies who participated in the public index and against the overall universe of participating companies. As a matter of fact, once defined, the percentage score is grouped into performance bands (platinum, gold, silver, and bronze), which make up the public CR Index annual ranking. Such index will be made publicly accessible on BITC website and with the media partners.

Benefits Deriving from Using CR Index in Absolute and Relative Terms

Basically, the CR Index is the only voluntary, business-led benchmarking index which encompasses all corporation divisions and reports on the four basic influence sections of corporate responsibility: community, workplace, marketplace, and environment, all together treated on an equal basis.

Differently from some other widely adopted indices such as Dow Jones Sustainability Index and the FTSE4 Good, CR Index works as a business instrument rather than an investment instrument (El-Masry and Kamal 2013). Moreover, unlike some indices such as the Carbon Disclosure Project and the London Benchmarking Group that are focused on just one influence area (respectively, the climate change and the community), CR Index is geared toward detecting CR performance in more than one influence area (El-Masry and Kamal 2013).

In absolute terms, benefits arising from using CR Index might be summarized as follows:

- It provides a tried and tested framework for the management of social and environmental issues.
- It helps identify good practice across the CR agenda in the form of a gap analysis.
- It focuses on nonfinancial risk management.
- It drives CR-related efficiencies and innovation.
- It facilitates communication and engagement with internal and external stakeholders.
- It enhances brand reputation.

- It demonstrates a strategic commitment to sustainability (BITC 2012).

To the abovementioned benefits, there should be added those ones deriving from exerting the Private Benchmarking option each participant may take advantage of. Indeed, beyond publicly available CR Index, participants may decide to resort to this confidential option, which allows them to compare against the CR Index participants without having to publicly disclose results.

Therefore, Private Benchmarking may provide companies with additional advantages such as fully flexible timeline, openness to all companies and sectors; guidance before and during self-assessment period; additional feedback for comprehensive baseline assessment; and no reputational risk (BITC 2012).

Summary and Future Directions: The Launch of the "Responsible Business Tracker"

Although each business found CR Index extremely valuable, in recent years there was a growing perception that changes in the responsible business domain and in sustainable development policy were causing CR index to lose its effectiveness progressively (BITC 2018). Hence, in Financial Year 2017/2018, basing on the feedbacks from members, BITC changed its approach to benchmarking and performance management. This has ended up with designing the new Responsible Business Tracker, generously supported by Sky and made possible also by counting on the assistance of Lloyds Banking Group Centre for Responsible Business at the University of Birmingham (BITC 2018).

The Responsible Business Tracker stemmed from a consultation with over 200 companies, nongovernmental organizations, government, and international partners. Following in the CR Index's vein, the Responsible Business Tracker stands as a measurement tool designed to enable a business to measure their performance as a responsible business. It provides a robust validation process with feedback tailored to the

Business in the Community Index, Fig. 2 UN Sustainable Development Goals (UN 2015)

organization, which informs an action plan with support from a Business in the Community adviser. Compared to the previous CR Index, the Tracker's unique selling point is that it covers the entire responsible business agenda, it is expected to cater to all sectors and sizes of businesses (whether listed or unlisted), and it aligns with the 17 United Nations' (UN) Global Goals, conceived as the Sustainable Development Goals (Fig. 2).

Sustainable Development Goals are to be pursued in compliance with the BITC Responsible Business Map reported in Fig. 3.

Based on the premise that the Global Goals campaign looks up to the UN sustainable development agenda of 2015 and aims to engage businesses everywhere to ensure that their core business model is a sustainable one, Tracker is intended to enable a business to contribute to the realization of the Sustainable Development goals by identifying the key issues that need to be addressed to ensure long-term financial value, enabling both society and the planet to thrive. After all, by looking up to the abovementioned Responsible Business Map, responsible business might be framed as one that puts creating healthy communities and a healthy environment at the

center of its strategy to achieve long-term financial value.

Differently from the CR Index, which popped up as a management and benchmarking tool based on a yearly basis cycle, the Tracker is a biennial tool. Indeed, a biennial cycle may enable organizations to focus and work on the feedback received from their Corporate Adviser in a timely fashion before embarking on the next cycle. Once again, Tracker offers benchmarking and recognition as well as gap analysis, highlighting best practice and allowing organizations to measure themselves against competitors (BITC 2018).

In 2018, BITC began to pilot the Responsible Business Tracker with 82 forerunner member companies from 26 sectors. Participants trialed the survey tool between September and December 2018 before receiving practical tips, examples of good practice, tailored advice, and an action plan from a Business in the Community adviser. The first full cycle of the Responsibility Business Tracker will take place in September 2019.

Overall, BITC vision is that global organizations of all sizes may give proof that mainstreaming sustainability and responsible

Business in the Community Index, Fig. 3 Responsible Business Map (BITC 2018)

business as part of their business model is the best route to commercial success and to deliver the Sustainable Development Goals by 2030 (BITC 2018).

Global organizations, on their parts, by taking into account the role of Responsible Business Tracker as a groundbreaking hub for employers, might achieve the Global Goals more easily through sharing expertise, shared learning, best practices, and recommended practical and strategic actions.

Business Judgment Rule

Benedict Sheehy
Canberra Law School, University of Canberra,
Bruce, ACT, Australia

Synonyms

Directors' defense; Directors' discretion

Definition

The business judgment rule is a rule in corporate law which provides directors of a business corporation a defense in lawsuits where corporate decisions have been challenged in the courts. The rule provides a defense where directors can demonstrate that they have acted in good faith. The rule is based on the general corporate law principle that the courts will not impose liability where a corporate decision has had negative consequences

for the company provided that the directors have acted in the best interests of the company when taking those decisions (Arsht 1979; Sheehy and Feaver 2014).

In essence, the business judgment rule protects a corporation's board of directors and allows it to function without wasting excessive time defending against frivolous litigation concerning the conduct of the corporation's business. The rule in common law countries provides that boards are presumed to act in "good faith" – i.e., boards are assumed to be operating in line with the obligations of loyalty, diligence, and care that directors have to the company. Thus, without clear evidence that a board has breached its legal duty, the courts will not review or overturn a board decisions about how to conduct the business of the company (Kim 1980).

Introduction

The business judgment rule is derived from a legal doctrine that is at least 150 years old in the common law world. It arose to ensure that decisions made by directors, officers, and controlling shareholders that were done in good faith would be allowed to stand even where those decisions led to poor results or were contrary to the will of the shareholders more generally. More recently, as a response to the rise of derivative actions in which directors' decision-making came under increasing scrutiny, the necessity of excusing honest directors took on a greater importance and led ultimately to law reform and a statutory enactment of the rule. It is important to note that each jurisdiction has distinct rules for its distinctive business judgment rule. The entry which follows is introductory only and readers looking for the specifics of the rule are directed to their specific jurisdictions.

The American Law Institute formulated the basic rule as follows:

A director or officer who makes a business judgment in good faith fulfils the duty under this section if the director or officer (1) is not interested in the subject of the business judgment; (2) is informed with respect to the subject of the business judgment

to the extent to which the director or officer reasonably believes to be appropriate under the circumstances; and (3) rationally believes that the business judgment is in the best interests of the corporation. (American Law Institute 1994)

Assumptions

The rule operates on certain assumptions. First, it is assumed that directors, officers and majority shareholders are executing their duties correctly – i.e., in good faith, with care and diligence. As a result, plaintiffs looking to challenge directors' decisions have to demonstrate a failure of directors in fulfilling their fiduciary duties. Second, it assumes that directors' decisions will not always be good decisions, that errors will be made and that even good decisions may result in poor outcomes. In other words, it is recognized that directors will not make optimal decisions (Bainbridge 2004). The consequence of this assumption is that directors are not unduly cautious and are willing to take appropriate risks knowing that the business judgment rule will shield them from liability in such instances.

Objectives

The basic objectives of the rule are twofold: (1) To provide assurance to directors that they will not be found to be liable for decisions taken where they have been taken on appropriate grounds. (2) As such, that protection granted to directors ultimately results in protecting corporations from frivolous lawsuits. This result eventuates because of legal presumption requires parties seeking to file lawsuits to prove that management is working against the interests of shareholders (Block et al. 1990).

Legal Principles and Business Decision-Making

The rule further implements a legal principle of judicial deference to directors and officers. That principle is that the judiciary will not interfere in

the internal affairs of the corporation in the absence of some type of fraud or other violation of the law. It recognizes that judicial expertise is in the interpretation and application of law whereas the expertise of directors and officers is in the evaluation and weighing of benefits and costs and related risks in business. Thus, unless there has been a violation of the law including a breach of duties, the court will not entertain a complaint about the decision made (Block et al. 1990).

Decisions made by directors and officers are complex, multifaceted, and have long-term implications. Furthermore, decisions are made with imperfect information – information that is incomplete, incorrect, outdated, or otherwise lacking desirable characteristics. Finally, these decisions are made in an environment dynamic marketplaces. As a result, there is no guarantee that the best of decisions will prove to be profitable, as is seen with failed mergers and acquisitions which may lead to significant financial losses (Weber 1996). Accordingly, it is entirely appropriate that these senior corporate decision-makers be excused from liability for decisions which do not turn out as planned.

The Delaware court has put the legal principle as follows: “Substantive second-guessing of the merits of the business decision. . .is precisely the kind of inquiry that the business judgment rule prohibits” (*In re The Dow Chemical Company Derivative Litigation* 2010 WL 66769 Del. Ch.).

In essence, therefore, the business judgment rule is an acknowledgement that business decision-making both in terms of long-term strategy and day-to-day operations involves uncertainty, contestable decisions, and putting the company's assets at risk, and includes making errors of judgment. Indeed, by their nature business decisions require an element of risk as part of the investment decision, whether starting a new product line or investing in a new venture. A general assumption in business is that higher profits require taking greater risks (Greenfield and Nilsson 1997; Johnson 2000).

In setting out the test for the business judgment rule, American courts use the *Aronson rule* (*Aronson v. Lewis*, 473 A.2d 805, 814, Del. 1984). It sets out two alternative tests. These are

either “The complaint must allege particularized facts that establish a reasonable doubt that ‘(1) the directors are disinterested and independent [or] (2) that challenged transaction was otherwise the product of a valid exercise of business judgment’” (cited in Goldberg 1999; Block and Prussin 1983).

Limitations and Criticisms of Business Judgment Rule

The business judgment rule is limited to situations where directors are seeking to defend against claims that they have breached their duties to act with care and diligence. The rule does not extend to breaches of other duties (Hansen 1993; Horsey 1994).

Further, the rule only applies to “business judgments.” In other words, it is limited to “any decision to take or not take action in respect of a matter relevant to the business operations of the corporation” (Carroll 1991). While this definition is relatively broad, courts have limited the scope of decisions that will be classified at law as “business judgments.” For example, the court has determined that decisions in areas of business planning, budgeting, and forecasting are business judgments. Further, the court has excluded common director activities like monitoring corporate affairs and understanding a company’s financial position, as not falling into the category of decision-making subject to a business judgment rule defense. As a result of such judicial interpretations, the business judgment rule does not provide a defense in all circumstances where judgment is required (Block and Prussin 1983; Horsey 1994). Finally, the business judgment rule only applies to actual “decisions.” Thus, for the business judgment rule to have potential application as a defense a director must positively turn his or her mind to the matter in question (Hinsey 1983).

Legislating the Business Judgment Rule

Although as noted, the business judgment rule has a long history, more recently, legislators have

begun to introduce statutory versions. The aim is to provide clarity and certainty for directors and officers acting properly in the discharge of their duties while recognizing the commercial reality of uncertainty in decision-making.

The rule takes account of the reality that no commercial decision has predetermined outcomes and that at times, business decisions will lead to financial loss and even business difficulty. While a subsequent review of the decision may find fault with some aspect of the decision, the law governing corporate decision-making is not aimed at punishing directors and officers who have made properly informed and careful decisions that failed to produce desired results. It is a legal method designed to provide support for diligent decision-making and remove unnecessary threat of review by courts of appropriate exercise of management discretion (Bainbridge 2004).

Summary

The business judgment rule is a rule in corporate law. It provides a defense to directors and officers who are seeking to avoid liability for decisions which have failed to produce the positive results planned or harmed the corporation. To invoke the business judgment rule as a defense, the following elements, found in the statutory form of the business judgment rule in most common law jurisdictions around the world, must be demonstrated by the director or officer. Drawn from the American Law Institute’s Principles of Corporate Governance, the elements are that the business judgment was made:

- In good faith and for a proper purpose
- With no material personal interest in the subject matter of the judgment
- After they informed themselves about the subject matter of the judgment to the extent they reasonably believed to be appropriate
- With a rational belief that the decision was in the best interests of the corporation

As the test is cumulative, a director or officer must prove all four elements to rely on the rule.

Definition/Description

This chapter provides an understanding of the business model concept in different settings. Starting with a focus on **traditional business model**, an overview of the range of definitions is given. Generally, a business model represents the relevant activities of a company and their relations with each other in order to create, deliver, and capture value (Zott & Amit, 2010; Osterwalder & Pigneur, 2010; Richardson, 2008; Wirtz, Pistoia, Ullrich, & Göttel, 2016). Business models consist of several **elements** which are discussed in the following section. The **Business Model Canvas** (Osterwalder & Pigneur, 2010) is known as a prominent tool in practice and academia alike and introduced in detail. Subsequently, the most prominent **patterns** of business models which are **freemium**, **long-tail**, and **multi-sided platforms** are presented using practical examples. Besides traditional organizations, **social enterprises** gained increasing importance during the last decades. For this purpose, the Business Model Canvas has been adopted to the **Social Business Model Canvas**. Due to the increasing pressure from the environment, organizations

need to *innovate* themselves in order to become more sustainable (Lacy & Rutqvist, 2015). In the third section it is shown how the concepts from traditional businesses can be transferred to *sustainable business and sharing economy* in particular. Therefore, the ReSOLVE framework can help organizations to innovate and align their business model with sustainability purposes (De Angelis, 2018; EMF et al., 2015). This chapter concludes with a practical application of the Business Model Canvas of BlaBlaCar as an organization in the sharing economy.

Understanding of Traditional Business Models

Defining Business Model

The concept of business model obtained considerable interest within practitioners and academic communities. It gained popularity in the 1990s as an own field of research alternative to more traditional management approaches (Amit, Zott, & Pearson, 2012; Baden-Fuller & Morgan, 2010; Wirtz et al., 2016; Zott, Amit, & Massa, 2011). Publications in the field of business models increased and it became so important that the *Long Range Planning* journal published a special issue on this topic including articles from Baden-Fuller and Morgan (2010), Teece (2010), and Wirtz et al., (2010), to name only some of them. However, despite the magnitude of research in this domain during the last years, no common definition has been agreed on. Zott et al. (2011) complain that that “the term business model in its current use is not one concept; it is many concepts” (pp. 1034–1035). Likewise, Wirtz, Schielke, and Ullrich (2010) criticize that the term business model is not applied coherently. Contrary, the term business models has been used in various specification such as technology, innovation management, strategy, environmental sustainability, and social entrepreneurship (Stampfl, 2016).

In line with the amount of literature a huge range of definitions and interpretations on the term business model can be found (Sparviero, 2019; Zott et al., 2011). More generally, Porter

(2001), describe it as “conception of how a company does business and generates revenue” (p. 73). Zott & Amit (2010) highlight the business model as system of independent activities (see also Amit & Zott, 2001). Similarly, Richardson (2008), Timmers (1998), and Wirtz (2020) consider relevant activities or the architecture of a business as central aspect constituting business models. Addressing and satisfying a customer need is another important issue that has been mentioned (Amit et al., 2012; Magretta, 2002; Teece, 2010; Wirtz, 2020). Richardson (2008) includes the term “strategy” and calls for clearly distinguishing these concepts from each other. Whereas a strategy strives for building and securing a competitive advantage compared to competitors (e.g., by conducting market analyses and analyzing positions in the market), business models relate to customers and the value they deliver (how activities implement a strategy) (Magretta, 2002; Stampfl, 2016). This relationship between business model and strategy is supported by Richardson (2008) underlying the business model’s executing role in realizing strategies. In a similar vein, Osterwalder (2004) argues that a business model is the “the strategy’s implementation into a conceptual blueprint of the company’s money earning logic” (p. 17).

Besides these different orientations of the selected definitions on business models, they all refer to the element of “value.” Zott et al. (2011) refer to “value creation” and “value capture” and argue about the interplay of both. Teece (2010) puts the customer into the focus and says that the customer is willing to pay for value that he achieves through the product and a need that is going to be fulfilled (see also Christensen, 1997). Likewise, Osterwalder and Pigneur (2010) put the value into the core of their definition of business model. Wirtz (2020) argues that a business includes components which lead to value-added and finally generating or preserving competitive advantage. An overview over the range of definitions on the concept of business models is given in Table 1.

Condensing the definitions provided above a business model represents the relevant activities of a company and their relations with each

Business Model, Table 1 Range of business model definitions (own illustration based on Stampfl (2016) and Zott et al. (2011))

Author	Definition “business model”
Amit & Zott (2010)	“We conceptualize a firm’s business model as a system of interdependent activities that transcends the focal firm and spans its boundaries. The activity system enables the firm, in concert with its partners, to create value and also to appropriate a share of that value.” (p. 216)
Amit et al. (2012)	“A business model is a bundle of specific activities – An activity system conducted to satisfy the perceived needs of the market , along with the specification of which parties conduct which activities , and how these activities are linked to each other.”
Chesbrough and Rosenbloom (2002)	The business model is “the heuristic logic that connects technical potential with the realization of economic value ” (p. 529).
Magretta (2002)	Business models “explain how enterprises work” and answer the following questions: “Who is the customer ? And what does the customer value ? It also answers the fundamental question every manager must ask: How do we make money in this business? What is the underlying economic logic that explains how we can deliver value to the customers at an appropriate cost?” (p. 87)
Osterwalder and Pigneur (2010)	“A business model describes the rationale of how an organization creates, delivers, and captures value .” (p. 14)
Richardson (2008)	A business model is “a conceptual framework that helps to link the firm’s strategy , or theory of how to compete, to its activities , or execution of the strategy. The business model framework can help to think strategically about the details of the way the firm does business.” (p. 135)
Teece (2010)	“A business model articulates the logic, the data and other evidence that support a value proposition for the customer , and a viable structure of revenues and costs for the enterprise delivering that value .” (p. 179)
Timmers (1998)	The business model is “an architecture of the product, service and information flows, including a description of the various business actors and their roles; a description of the potential benefits for the various business actors; a description of the sources of revenues .” (p. 4)
Wirtz (2020)	“A business model is a simplified and aggregated representation of the relevant activities of a company. It describes how marketable information, products and/or services are generated by means of a company’s value-added component . In addition to the architecture of value creation, strategic as well as customer and market components are considered in order to realize the overriding objective of generating and preserving a competitive advantage .” (p. 57)

other in order to create, deliver, and capture value (Zott & Amit, 2010; Osterwalder & Pigneur, 2010, Richardson, 2008; Wirtz et al., 2016).

Business models are applicable on several levels, such as companies, business units, or products and services. Literature mainly refers to the organizational level, namely the company. Business models deliver several benefits for the organization. By implementing a business model, competitive advantages can be reached since an existing business model makes it harder to be copied by others. Similarly, existing and transparent business models contribute to a company’s unique selling proposition. The

organization delivers unique value to the customer which increases customer loyalty and retention. Moreover, business models provide an overview on success and costs as well as risks which increase strategic flexibility (Wirtz et al., 2016).

Elements and Components of Business Models

Business models can be depicted including several elements or components, ranging from only a few ones (2–3) to a more complex picture (9–11). There is a consensus in the scientific community that the business model reflects a company’s internal resources and capabilities as well as

corresponding transactions in the course of value creation (Amit et al., 2012; Teece, 2010).

Richardson (2008) argues that business models include three main components which are value proposition, value creation and delivery, and value capture. Wirtz's (2020) business model resembles the value chain by including elements such as procurement, finance, value creation, market offer, revenue, customer, and three subordinated models: strategy, resources, and network (p. 199).

Gassmann, Frankenberger, and Csik (2013) developed the Business Model Navigator comprising a triangle and four elements which are who (who is your target customer?), what (what do you offer to the customer?), how (how is the value proposition created?), and value (why does this business model generate profit?). This concept resembles the work of Markides (1999) who referred to the three dimensions what, who, and how when illustrating a business model. By doing so, the authors set the customer into the core of their analysis (who-dimension), the company's bundle of products and services satisfying the needs and adding value to the customer (what), the organization's internal processes and resources as well as the value chain (how), and finally the financial viability reflecting the revenue model (costs and revenues).

When comparing the different approaches and frameworks, even if the number of elements and components is differing from each other, the content is similar to each other (Stampfl, 2016).

Most prominent is the work from Osterwalder and Pigneur (2010). The authors developed the Business Model Canvas, a tool for academic and practitioners alike, to evaluate company's profitability. The ontology of the Business Model Canvas has been already developed in Osterwalder's dissertation in 2004. In the latest and highly cited version from 2010, Osterwalder and Pigneur present the result after having collaborated with 470 practitioners from 45 countries. The success is tremendous, since the concept has prominent position in academia and practices alike. It has been translated in over 30 different languages and increasingly cited on Google Scholar. The Canvas from Osterwalder and Pigneur (2010) is

chosen to be introduced in more detail since it presents a profound visualization of the business. It has been used extensively because it allows to experiment and theoretically reconfigure the elements (Chesbrough, 2010). Moreover, it facilitates creative thinking and teamwork. The Business Model Canvas includes nine building blocks (see Fig. 1). The nine building blocks and the core questions can be found in Fig. 1. When applying the Business Model Canvas, in a first step each of the nine building blocks is considered individually (a suggestion might be provided by the numbers in the boxes). Following, interdependencies are taken into consideration so that the whole picture can be created. More generally, these nine building blocks can be differentiated in the commercial model (focuses on addressing new demand, customer segments, customer relationships, channels, and revenue streams) and the operational model (refers to supply, key activities, key resources, key partners, and cost structure) (Osterwalder, 2004; Osterwalder & Pigneur, 2010).

Patterns and Typologies of Business Models

Typologies can be used to develop design guidelines for practical applications. A typology or pattern is helpful in order to identify common elements and summarizes them into groups. For business models, several typologies have been presented (e.g., Wirtz, 2020; Zott et al., 2011). **Malone et al. (2006)** focus on the rights that a company possesses (creator, distributor, landlord, and broker) and combined them with the underlying assets (financial, physical, intangible, and human). **Zott and Amit (2010)** develop the *NICE design themes* referring to the four components: novelty, lock-in, complementarities, and efficiency. Business models focusing on *novelty* refer to adopting new activities, including new participants, and developing new ways to link or manage these activities. As an example, the authors mention Apple introducing iTunes and iPod into the market. By doing so, Apple was the first distributing music integrating this activity into its business model. *Lock-in* refers to the customer retention in terms of high switching costs or network externalities (e.g., loyalty

Business Model, Fig. 1 Business Model Canvas (own illustration according to Osterwalder & Pigneur, 2010)

programs which retain customers to an organization). **Complementarities** is given if the bundle of two products/services provides higher value to the customer than selling them individually. Fourth, the authors explain **efficiency** as another criteria. Efficiency is present, e.g., in case of Internet online platforms such as [booking.com](https://www.booking.com) where search costs are reduced by decreasing information asymmetries (Zott & Amit, 2010).

Gassmann, Frankenberger, and Csik (2015) provide a more detailed typology of business models by differentiating 55 patterns. They include more prominent types such as freemium and long tail, but on the other hand very specific patterns. As such, reverse innovation is rather rarely applied, but very important. It means that a product or service has been explicitly designed for emerging markets purposes, and is then introduced into industrial markets (Govindarajan & Ramamurtin, 2011). As an example, the GE Healthcare MAC, a portable and small ECG, has been specifically invented for emerging countries.

Studies as well as practical use of the different types of business models have shown that freemium, long-tail (including subscription), and multi-sides platforms are to most promising ones. This is why they are considered more detailed.

Freemium has a long history and reaches back to the year 1845 where Peter Cooper applies a patent for gelatine in powder form. He sold it to Frank Woodward who tried to sell the powder but was not successful. The customer was not used to it and did not know which purpose it should fulfill. Thus, he wrote a book with many recipes and gave it for free in order to generate a huge customer base. Customers needed to buy the powder in order to cook the recipes. This model is also known as Razor and Blade model (razor is useless without blades) and is applied heavily (e.g., cell phone for free when signing a contract, Skype is generally free but charges in app fees) (Anderson, 2009; Teece, 2010). Freemium is often combined with subscription. A customer pays a regular fee and receives a product or service and the company can benefit from a regular income stream (example: newspaper).

Long tail is another important pattern characterized by Anderson (2008). So far, businesses acted according to the principle of scarcity. They concentrated on the top 20% of products which could be sold at high volume, so high popularity. The long tail explicitly focuses on the remaining part of products with the huge amount of least popular items (e.g., songs and books). Through

the Internet and digitalization it became attractive to also address these customer segments which present a kind of niche and were not so attractive to invest in before. Prominent examples are Netflix, iTunes, or Youtube: special clips could be uploaded, shared, and downloaded at low costs and satisfy a customer need (Anderson, 2008).

Through digitalization **multi-sided platforms** gained increasing attention. According to Osterwalder and Pigneur (2010) “multi-sided platforms bring two or more different customer groups together. Such platforms are only of value to one customer group if the other customer group is also present.” (p. 77). Literature on multi-sided platforms goes back to network economics research stating that an increasing network size offers benefits to the parties (Rochet & Tirole, 2003). Multi-sided platforms combine both, direct and indirect network effects. A single user can generate more value when the user group is large (e.g., Skype, all of friends are also on Skype), which is the direct effect. Indirect network effect means that the value increases in case another user group is also present in the market (credit card market: value for both parties, company and owner, is dependent on the other). The interaction between both parties is an essential criterion for generating value (Osterwalder & Pigneur, 2010).

Social Business Model Canvas

The Business Model Canvas has originally been developed for commercial or traditional organizations. However, during the last decades, social enterprises have been increasingly entered the market. “Social entrepreneurship typically refers to the phenomenon of applying business expertise and market-based skills in the nonprofit sector” (Austin et al., 2006, p. 2; see also Social Entrepreneur). They represent an important pillar of the three pillars of sustainability. Alter (2007) provides a typology for social enterprises and summarizes nine types. Prominent examples are, e.g., the Grameen bank (entrepreneur support) supporting local entrepreneur with microcredits (see also Microfinance).

According to Osterwalder and Pigneur (2010), the Business Model Canvas is not only designed for for-profit companies, but also to analyze those organizations that “have strong non-financial missions focused on ecology, social causes and public service mandates” (p. 264). The Business Model Canvas can be adopted in so far that the triple bottom line is (see also Triple Bottom Line) incorporated into the framework. Therefore, the authors suggest adding two further building blocks, namely social and environmental costs and social and environmental benefits, in order to take the additional value those organizations generate into consideration (Osterwalder & Pigneur, 2010). The Social Business Model Canvas can be found in Fig. 2.

Social enterprises face specific challenges as compared to traditional businesses (Jamali, Yianni, & Abdallah, 2011, see also Koschmann, Kuhn, & Pfarrer, 2012). They need to explicitly set up and actively communicate their **mission**, in addition with the need to blend and combine social and economic **objectives**. Furthermore, they translate these objectives into measurable **impact** and **output** (Emerson, 2003; Sparviero, 2019). Regarding their partners, social enterprises distinguish between **nontargeted stakeholders** (i.e., partners and affected stakeholders) and **targeted stakeholders (i.e., customers and beneficiaries)**. Finally, social enterprises establish organizational **governance** mechanisms in order to check whether they achieved their mission and objectives. Sparviero (2019) analyzed these characteristics of social enterprises and integrated them into the traditional Business Model Canvas. The enlarged version as well as a practical example is provided by Sparviero (2019, p. 246).

Business Model Innovation

Defining Business Model Innovation

Influences from the environment such as digitalization or changing society makes the need for adapting a business model faster and more radically than ever before. Once a business model has been developed and executed, a company might face the challenge how to develop the existing

Business Model, Fig. 2 Social Business Model Canvas (own illustration according to Osterwalder & Pigneur (2010) and Sparviero, 2019)

business further. It is important to search for new revenue streams and value creation (Hamel, 2000). By doing so, new and maybe unknown customer needs can be detected and addressed (Osterwalder & Pigneur, 2010). Underlining the importance of business model innovation, Wirtz et al. (2010) argue that “current business model should always be critically regarded from a dynamic perspective, thus within the consciousness that there may be the need for business model evolution or business model innovation, due to internal or external changes over time.” There are several strategies and methods in order to innovate a business model. Either the commercial model can be optimized by, e.g., using digitalization in order to improve sales (e.g., marketing, sales, and supply chain). On the other hand, the operational model might be enhanced by, e.g., improving the internal structure and processes as well as production site. Completely re-innovating or disrupting (see also Disruptive Innovation) a

business model is another solution (see, e.g., Christensen, 1997) which refers to Schumpeter’s process of creative disruption (Schumpeter, 1934).

Sustainable Business Model

The concept of sustainability was constituted by the report of the Brundtland Commission (see also Brundtland Report), the United Nations World Commission on Environment and Development of the United Nations. In 1992, the UN Conference on Environment and Development decided to strive for sustainable development which was confirmed as a result of the UN Climate Summit in Paris in 2015. These goals have been determined within the 2030 Agenda for Sustainable Development, with **17 Sustainable Development Goals (SDG)** (see also Sustainable Development Goals [SDGs]) at its core, at the UN Sustainable Development Summit in September 2015 (United Nations, 2015). In contrast to the Millennium

Development Goals focusing on the social dimension of development, the SDGs were introduced to emphasize the issue of sustainability. The target is to reach a **circular economy**. This concept describes those resources can be used more than one time (Gallaud and Laperche (2016). “A circular economy thus provides opportunities to create well-being, growth, and jobs, while reducing environmental pressures. The concept can, in principle, be applied to all kinds of natural resources, including biotic and abiotic materials, water and land” (European Environment Agency, 2016, p. 9.; see also Environmental Sustainability Index [World economic forum]).

According to Elkington (1997), sustainability strives for reaching economic, ecologic, and social value (see also John Elkington). Society expects organizations to strive for sustainability and to take the lead in addressing these problems. Taking this challenge and addressing the issue of sustainability in a business model can result in competitive advantage and better reputation, increased customer loyalty reduced supply costs and risks (Lacy & Rutqvist, 2015). In order to include sustainability into a business model, the traditional business model needs to be transformed to a sustainable business model. EMF et al. (2015) proposed the **ReSOLVE framework** which means regenerate, share, optimize, loop, virtualize, and exchange (EMF et al., 2015, p. 25). The meaning and examples of the principles can be found in Table 2.

A sustainable business, e.g., uses materials that are fully recoverable, and most probably the supply chains will be more local and regional due to closer material loops and less geographical barriers (Lacy & Rutqvist, 2015; WEF et al., 2014; see also Sustainable Business Model). The business model no longer focuses on customers possessing products, but leasing those (e.g., domestic appliances). It will evolve from ownership to lending and the value creation is more about the service because this will generate the main revenue (De Angelis, 2018; EMF, & McKinsey, 2012). Today this is possible with, e.g., renting photovoltaic plants at EON.

As in the case of social enterprises, the frameworks and typologies can similarly be transferred to sustainable business models. Most of the 55 patterns that Gassmann et al. (2015) presented can be applied to sustainable businesses alike (e.g., De Angelis, 2018). Out of the 55 patterns, only a few types such as shop-in-shop or direct selling cannot be applied to sharing economy since they are particularly tailored to purposes of commercial organizations. Others do not fit to sustainable targets at all (flat rate). Other patterns such as open source, renting instead of buying, or reverse innovation clearly refer to sustainable business models (see also Reverse Innovation).

Sharing Economy Business Model

In line with the SDGs and the focus on social as well as sustainable business models, sharing

Business Model, Table 2 Own illustration in reference De Angelis, 2018; EMF et al., 2015

	Meaning	Example
Regenerate	Renewable materials and sources of energy	Pottburri compostable packaging
Share	Sharing goods among users, also along the product life cycle by, e.g., repair	Airbnb
Optimize	Improves product and processes efficiency	Renting clothes (Kleiderei in Berlin)
Loop	Returning technical materials to use (e.g., repair, remanufacturing, and recycling)	Miele (long-lasting washing machines)
Virtualize	Delivering utility in the absence of physical products (e.g., online music and books)	Spotify and iTunes
Exchange	Use of innovative technologies and materials enabling more resource-efficient industrial processes	Daimler Car2go (also share)

economy became more and more attractive in recent years (Curtis, 2021; see also Sharing Economy). Sharing contributes to reducing the waste of resources by giving products another life cycle. The concept is also known as collaborative consumption (Botsman & Rogers, 2014) or peer-to-peer economy (Miao, Lin, Wei, & Moon, 2021). Another synonym is *co-consumption* which is “made by the activities of sharing, exchanging and rental of resources without owning the goods” (Nah & Tan, 2017, p. 174). Another definition for sharing economy is provided by Botsman. “An economy built on distributed networks of connected individuals and communities versus centralized institutions, transforming how we can produce, consume, finance and learn” (Botsman, 2013). Highlighting the use of Internet platforms, Apte and Davis (2019) understand sharing economy as a new way of business by using cloud-based technology to connect customers and the providers. Changing consumer preferences such as the willingness to share, new technical possibilities due to the Internet and digitalization as well as social networks allow sharing economy to grow.

Three different types of share economy can be distinguished from each other. **Redistribution markets** mean that online market places enabling goods no longer needed by their original owner to be reused elsewhere (e.g., Ebay and Vinted). **Product-service systems** allow people to receive the benefits of a product without having actually own it themselves (e.g., Airbnb, Spotify, and Car Sharing). **Collaborative lifestyles** extend the product-service systems from physical goods to the sharing of time, skills, space, and money generating the additional benefit of exchanges on a local or regional scale (e.g., Taskrabbit, BlaBlaCar, and Neighborhood Fruit) (Botsman & Rogers, 2014).

The Business Model Canvas is also applicable to sharing economy. An example is given in Fig. 3 with the organization BlaBlaCar.

BlaBlaCar has been established in 2006 in France and is a community-based traveling network with currently over 90 million members worldwide. It is a traditional organization of sharing economy since they allow passengers to benefit from the product they do not own (car) themselves. Additional benefit is generated

Business Model, Fig. 3 Business Model Canvas in sharing economy on BlaBlaCar. (Own illustration based on BlaBlaCar, 2021 and Elisei, 2016)

through the sharing of time (talking during the trip, “blablabla”) (Blablacar, 2021; Elisei, 2016).

The example demonstrates that the Business Model Canvas is similarly transferred to organizations from sharing economy. However, there are three building blocks of customer segments, value proposition, and key partners (highlighted in green color in Fig. 3) which gain particular importance. Sharing automatically brings previously anonymous people together, in this case driver and passenger. These different perspectives need to be incorporated in the sharing economy Business Model Canvas.

Definition

The capacity of innovation is understood as the ability of an actor to do innovation. Thus, at

territorial level capacity for innovation it is the innovative capacity of a territory. The capacity of innovation or innovation capacity is related to the determinants that affect innovation ability at territorial level.

Suarez-Villa (1990) introduced the concept of capacity of innovation to measure the invention and innovation potential of a country, to know its real situation in terms of innovation and to provide relevant information for both policy-makers and academics.

At the national level, for Natário et al. (2007) the ability to innovate is an evolutionary process and it is related with the performance and innovative capacity of countries. This capacity involves divers' factors of invention, such as education and formation, research and development (R&D), the protection of intellectual property and innovation systems.

The national innovation capacity is the main driver of economic performance and measuring institutional structure achievements. This involved the innovation systems, institutional infrastructures and support systems that sustain innovation activities (Mathews and Hu 2007).

Innovation capacity is about the dynamics of the country to transform knowledge into innovation, and to generate long-term prosperity (Furman et al. 2002; Natário et al. 2011; Chaminade et al. 2018; Weresa 2022). The concept relates to innovative performance and relates to the impact of institutional efficiency, the role of national culture, the influence of innovation

infrastructures to support innovation capacity, financial support for innovation and the cooperation links and networks used to stimulate/promote innovation capacity (Natário et al., 2011).

Pavão et al. (2019) consider the capacity for innovation depends to the autonomy regional governance; the effect of latitude geography; the role of central and peripheral; and the European Union's (EU) regional development policy, embodied in the criteria for cohesion policy.

Innovation capacity in the countries changes over time and can be influenced by internal and external factors. The key internal factors include R&D expenditure and its structure, human resources for research and development activities as well as innovation policy incentives. The main external factors are related to the international trade of high-tech goods, foreign direct investment and international mobility of R&D personnel (Weresa 2022).

Innovation capacity studies are carried out to understand the fundamental factors and determinants of innovation dynamics and capacity to develop innovation. They strive to understand what factors are key to stimulating and promoting territorial innovation and see innovation as a key role in competitiveness. The aim is to identify the most important factors in the development of innovation policies that promote innovation dynamics and innovation systems.

Also, the studies in this area of innovation are intended to be a guide for researchers, practitioners doing business and policy-makers to support the design and implementation of strategies and policies capable of boosting innovation capacity at different levels: international, national and regional. They examine the factors of innovation success and offer recommendations for future policy actions (Kowalski 2022).

Introduction

Territorial competitive advantage depends on its ability to innovate in relation to its innovation dynamics. Areas supporting innovative attitudes have improved their capacity for innovation and promoted competitiveness. Innovation is the basis for the development of strategic benefits. Innovation capacity allows areas to increase their productivity and attract investment, thereby maintaining the continuous development of quality and living standards (Natário et al. 2012).

Key Issues

Many authors have focused on enriching analysis and clarifying the concept of innovation capacity using different approaches (Howells 2005; Schiuma and Lerro 2008; Natário et al. 2011; Pavão 2014; Weresa 2022) (see Fig. 1).

At national level, the capacity of innovation can be understood as the characteristics and factors that distinguish countries or groupings of countries, which, through the application of techniques of quantitative analysis, such as cluster analysis, allows to identify them. For Furman

Capacity of Innovation, Fig. 1 Approaches of Innovation Capacity. (Source: Adapted from Pavão (2014) and Weresa (2022))

et al. (2002), the concept of national innovation capacity encompasses three approaches: (i) the theory of endogenous growth based on Romer's ideas (1990); (ii) the theory of industrial clusters based on the competitive advantages of Porter (1990); and (iii) the approach of national systems innovation developed by Lundvall (1992), Nelson (1993) and Edquist (1997).

On the basis of the three approaches mentioned above, Furman et al. (2002) developed a model contemplating the following determinants of national innovation capacity:

1. Common infrastructure (common institutions, resources committed, policies that support innovation); according to López-Fernandes et al. (2012), this set of determinants is comprised of the investments that support innovative activities that affect all activities of the innovation-oriented economy.
2. Specific conditions of cluster in the nation (the particular environment of innovation in industrial clusters of the nation). Although the common infrastructure establish the overall context for innovation, they are the companies, influenced by its microeconomic environment, that developed and market innovations. Diamond-based Porter (1990) recognized four main elements of this microeconomic environment: the presence of highly skilled inputs, a context that encourages investment and intense local rivalry, demand conditions and the presence of related and supporting industries.
3. The quality of relations between the previous categories (capacity to channel research for companies, collective efforts which will contribute to the entire set of technology and trained personnel).

The interaction between these three determinants is key to promoting innovative performance in economies.

At the national level, innovative performance and capacity of innovation, according Natário et al. (2011), depends on five country ecosystems:

1. Institutional ecosystems based on the efficiency of the institutions

2. National culture
3. Innovation's infrastructures: human resources, workers'skills in innovation and technology
4. Finance resources for innovation
5. Linkages and cooperation networks to stimulate/promote the innovation capacity

The capacity to create linkages toward several actors of national or regional innovation systems are crucial to stimulate innovation capacity.

At the regional level, territorial innovation capacities depends, following Natário et al. (2012), on the dynamics of each region in the following factor dimensions: (1) the collective training innovation infrastructure; (2) financial sources of innovation; and (3) cooperation networks.

For Chaminade et al. (2018) natural resources and environmental impacts and the sustainable are dimensions that influence innovation systems and also sustainable innovation capacity.

Pavão et al. (2019) have added additional relevant dimensions to the study of the subject at the regional level, focusing on four new dimensions, the first on the impact of regional autonomy on regional innovation capacity, the second, the geographical location dimension, where it is used to measure the impact of width on innovation capacity, the third dimension is the comparability of the accessibility index or binomial centre relative to the periphery, finally, it informs it of centrality through the European Union's (EU) regional development policy embodied in the criteria for cohesion policy.

The international dimension, with respect to external factors as international trade, high-tech trade, foreign direct investment (FDI), and international mobility of human resources, in particular R&D resources, was introduced by Weresa (2022) in order to analyse the innovativeness at the national level.

More recently, also McCaleb (2022) identified the national and regional level determinants of innovation capacity. The aim of this study is to contribute to the definition of strategies, policies and instruments capable of promoting innovation capacity at regional and national levels.

Thus, at the national level, the key factors to promoting innovative capacities are: the central

government's provision of policy, financial and regulatory support, the size and sophistication of the domestic market, the expenditures on R&D, the quality of higher education, R&D personnel and culture. At the regional level, innovative capabilities were influenced by inflows of FDI, local governments agile in creating innovative ecosystems and venture capital (McCaleb, 2022).

Future Directions

New directions of future research can be achieved through a new nature of the economic specialisation of regions or as an impact of innovation on the public sector. Studies on innovation in services are recent and new in the public sector. It is therefore important for countries and their innovation capacities to analyse the public sector innovation process and its impact on the innovation capacity of the territories.

The sustainability of innovation capacity associated with natural resources and environmental factors and with social responsibility will be a field of research of special interest and very important given the profound climate changes.

Carbon Balance

Antonio Castrofino
Unitelma Sapienza University, Rome, Italy

Synonyms

Carbon cycle; Global carbon cycle

Definition

“Carbon balance” is defined as the balance of carbon flows within a specific “carbon cycle” or at the level of the “global carbon cycle.”

Introduction

The carbon cycle involves three “districts” of the Earth: the hydrosphere, the biosphere, and the atmosphere. These districts are called “carbon sink” and are linked together in what is the natural cycle. A fourth carbon sink “district” is that of the

geosphere, in which carbon settles in tens of millions of years and becomes fossil fuel or fossil carbon (Ferrara and Ferrugia 2007). However, the geosphere has no natural connection with the remaining three districts, and the carbon accumulated in it does not come out naturally. The human factor has created an artificial connection “tube” between the geosphere district and the atmosphere, thus connecting the fourth district to the other three, leading to an imbalance between the flows: the carbon released by the geosphere does not return there (at least not before millions of years) and affects the balance of the natural cycle.

The carbon balance, therefore, is used to calculate excesses or defects of these flows and will be important in the near future to try to build solutions to reach new equilibrium phases in the global carbon cycle or a specific cycle. Overcoming the ongoing climate changes also strongly depends on this balance.

The Balance of the Carbon Cycle

The carbon cycle is closely linked to the climate and its transformations and is made up of physical, chemical, and biological phases. This cycle foresees that the plants on Earth through the chlorophyll photosynthesis absorb carbon dioxide. The biosphere through the respiration of plants and animals (consumption of oxygen “O₂” through cellular respiration and production of carbon dioxide “CO₂”), through their decomposition and natural fires, releases carbon into the atmosphere.

Similarly, in the hydrosphere, a close relationship is created between the amount of carbon dioxide present in the air and that dissolved in the water (Post et al. 1990). This presence is due to the pressure created on the surface of the water. In fact, if the exchange coefficient (speed of the molecule to move) of the gas changes, the surface of the water, in turn, releases CO₂ into the atmosphere. Just as in the biosphere, living organisms in water also absorb CO₂, the most important phytoplankton of all.

The percentage of CO₂ in the atmosphere, calculated in parts per million, has grown at a

dizzying rate in the last century. Thanks to the coring carried out by scientists in Antarctica, it is possible to know that at the beginning of the 1800s, there were 280 ppm of CO₂ (pre-industrial age), while today the instruments record the data of 411 ppm, recorded in December 2019. The explanation of this increase is the human activity which in the industrialization and growth phase developed a strong dependence on fossil fuels which, until then, were kept inside the subsoil. These fuels have put into circulation “ancient” stable carbon, without its radioactive part “carbon-14 (¹⁴C),” creating an important imbalance in the carbon cycle. It was the Austrian Hans Suess who studied the variation between the atmospheric concentrations of carbon isotopes (¹³C and ¹⁴C) with the dilution of large quantities of CO₂ from fossil fuels and then discovered that it runs out in ¹³CO₂ without containing the ¹⁴CO₂ radiocarbon that is reused in chlorophyll photosynthesis from plants (Suess effect).

The carbon balance within its natural cycle was previously constant over time. If an excess of carbon had occurred within one district, a defect would have occurred in another. This balanced state of balance, however, changed with the external insertion of carbon from the geosphere, extracted by the human being to conduct its activities.

Until the 1970s, part of the excess carbon was reintroduced into the carbon cycle, thanks to the absorption of the biosphere and hydrosphere. However, these absorptions, which still occur today, do not appear, from the balance sheets, to be sufficient for the current rate of extraction and human use of fossil fuels. In the 1970s, the maximum possible absorption levels at the natural level were reached, calculated at around 3000 megatonnes of carbon, and since then it is possible to observe a strong acceleration of the concentration of carbon in the atmosphere (analyzed in CO₂).

In 1827 the French mathematician Jean-Baptiste Fourier for the first time used the term “greenhouse effect” to illustrate how even minimal changes in the atmosphere could alter the climate of the planet. In truth, the greenhouse effect is a natural phenomenon, thanks to which

an average temperature on the planet of about 15 °C is possible. In the absence of a greenhouse effect, life on Earth would not be possible (the average temperature on the planet in the absence of a greenhouse effect is estimated to be around –18 °C on average) (Pasini et al. 2006).

The gases that allow the greenhouse effect (therefore called “greenhouse gases”) reabsorb part of the energy re-emitted from the soil, and in the atmosphere, there is a greater amount of energy than the incident solar energy. Because of this and because of the energy released by the same gases, previously accumulated, the temperatures rise strongly. These gases are methane (CH₄), nitrous oxide (N₂O), ozone (O₃), chlorofluorocarbons (CFC), and carbon dioxide (CO₂).

The balance of climate-changing gases and CO₂ emissions are the subject of great attention by the scientific world because the future of the planet will depend on how much the human being will be able to stabilize its activities by keeping the concentrations of CO₂ equivalent in the atmosphere at a sustainable level.

Key Issues

The excess of carbon dioxide in the atmosphere, and consequently in the other three land districts, has increased global temperatures, thus creating a global climate change. Scientists around the world agree that it is the man with his activities who is the primary cause of this excess and that a solution is needed as soon as possible.

Future Directions

The future of the planet and mankind will depend on how much emissions from human activities affect climate events and the increase in global temperatures.

In this future, the analysis of the carbon balance and its cycle will be fundamental to try to understand the optimal direction to take for a readjustment of the economy and human life on earth.

The carbon balance and its cycle must always tend in a balanced and balanced state. The human being must predict awareness that planet Earth is not able to sustain for a long time the development activities without limit and the exploitation of reckless natural resources.

Scholars from all over the world question themselves every day trying to find alternative answers to the economic theories that today are prevailing and globally recognized as valid for the well-being of human civilization.

Tending toward a “carbon-free” development that allows the balance between emissions and absorptions to be brought to zero is the objective to be put in place in the political, economic, and social forums. A new way of thinking about human life, which has less impact on the carbon balance, will require an increasingly greener economy.

Reforestation is an important step that many countries around the world have decided to take to create green lungs capable of supporting current emissions even more. On the contrary, large farms, overfishing, and intensive cultivation are still a major global problem to which the governments of the main industrialized and developing states are not giving due weight (Brown 2009).

The transport sector, especially the automotive sector, being one of the sectors with the most important emissions, has taken on the concept of sustainable mobility and sharing economy in recent decades, with the inclusion of hybrid and electric cars in the global market and with important international brands that have focused on “carsharing”

The design of increasingly energy-efficient houses and buildings will also reduce emissions and waste of energy in the construction and residential life sector.

New technologies, renewable energy sources to be increasingly replaced by fossil fuels, will have to allow for greater energy efficiency in all sectors, from industrial to corporate, from the public to private, only in this way will it be possible to achieve important results on CO₂ emissions balance. Applying the new concepts of circular economy and bioeconomy will be

fundamental to start producing bioenergy and biomaterials.

The carbon balance in this will be fundamental to understand to every human action how the natural plant and ocean system will respond, which is what will happen to every change of CO₂ and climate. It will be necessary to observe the global biogeochemical-climatic system with extreme attention, communicate the results of these observations to the institutions, and ensure that human, economic, and social choices adapt to the balance necessary to stop climate change.

Summary

The stability that the balance of the carbon cycle in nature had in the past has been changed by the activities of the human being. The central pivot of these activities is the development of industrialization based on the exploitation of resources, especially of fossil fuels. This exploitation has increased the concentration of carbon dioxide, both in the biosphere and in the hydrosphere, thus increasing the greenhouse effect and temperatures, causing ongoing climate changes and jeopardizing global climate balances. Knowing the functioning of the carbon cycle, the human being must aim at solving the problem through policies that aim at a new balancing of the cycle, regulating emissions on the basis of absorption capacities, in order to adapt its activities to current changes and, by contrasting them, avert the possible catastrophic consequences for life on Earth.

Carbon Disclosure Project

Isabel-María García-Sánchez and
Jennifer Martínez-Ferrero

IME (Multidisciplinary Institute for Enterprise),
Facultad de Economía y Empresa, Edificio FES,
Universidad de Salamanca, Salamanca, Spain

Definition

Carbon Disclosure Project (CDP hereinafter) is a nonprofit organization that directs the global disclosure system for investors, companies, cities, states, and regions in order to manage their impact on the environment. It was created in 2000 at the initiative of a group of 35 institutional investors interested in incorporating information on business' carbon emissions into their analyses and assessment (Depoers et al. 2016, p. 446).

Introduction

Carbon Disclosure Project (CDP hereinafter) is a nonprofit organization that directs the global disclosure system for investors, companies, cities, states, and regions in order to manage their impact on the environment. It was created in 2000 at the initiative of a group of 35 institutional investors interested in incorporating information on business' carbon emissions into their analyses and assessment (Depoers et al. 2016, p. 446).

Climate change, water scarcity, and deforestation are unprecedented global challenges that demand a systemic change in market behavior. To achieve this, CDP directs the global disclosure system that allows companies, cities, states, and regions to measure and manage their impact on the environment. In this regard, over the past 15 years CDP has created a system that has resulted in unparalleled engagement on environmental issues between investors, companies, cities, states, and regions worldwide. CDP's data enables our network to link environmental integrity, fiduciary duty, and public interest to make better-informed decisions on climate action.

Following Depoers et al. (2016) and Stanny and Ely (2008), the CDP has two main objectives: (i) sending an annual questionnaire, supported by institutional investors, to the world's largest firms by market value for informing managers of investor's concerns over climate change; and (ii) by making individual responses available at its website, the CDP can produce reports with aggregate responses for informing investors of firm's climate change-associated risks. Reid and Toffel (2009, p. 1163) describe the CDP as "...the largest repository of corporate greenhouse gas emissions data in the world," making it internationally significant and influential (Andrew and Cortese 2011).

According to Depoers et al. (2016), the main differences with respect to the traditional corporate reports are that the CDP audience is the firm's investors; the basic purpose of the CDP is the disclosure of the volumes of firm's climate change actions – for instance, greenhouse gas emissions; the scope of reported emissions in the participation in the CDP requires the broadest scope

possible; with respect to the method used for calculating greenhouse gas emissions, the CDP established a free choice of method but with a greenhouse gas emission protocol recommended; the presentation of greenhouse gas emissions requires a specific format following the usual calculation standards; and, finally, the CDP requires a required format with a set of questions related to the amounts of emissions reported.

The procedure is as follows. Every year the CDP asks firms, cities, states, and regions for data on their environmental performance, for instance, their greenhouse gas emissions, emission reduction targets, and climate change risks, opportunities, and management strategies, by answering the CDP questionnaire (Kim and Lyon 2007). Then, the CDP transforms that data into detailed analysis on critical environmental risks, opportunities, and impacts. Companies' responses are made publicly available on the CDP website. Finally, investors, businesses, and policy makers use its data and insights to make better decisions, manage risks, and capitalize on opportunities. At this respect, over time, CDP has tried to reinforce the reliability and comparability of its data – for instance, regarding comparability, CDP has tried to make a distinction between activity sectors, requesting more information to those carbon-intensive activity sectors. Moreover, as Matisoff et al. (2013) highlight, changes in the CDP format often seemed reasonable, because, for instance, it has moved from open-ended responses to multiple-choice answers that force firms to provide specific types and formats. For it, questionnaires have been modified and improved in the last years and paid more explicit and specific attention to emission trading and quantitative data (Kolk et al. 2008). CDP has also increased the number of items analyzed related to strategy, governance, and management.

As this organization highlighted, the CDP operates in most major economies worldwide and channels information and progress through individual programs. These are climate change, water, supply chain, forests, and cities. Its carbon action initiative encourages investors to accelerate carbon reduction in high-emitting industries and to implement emission-reducing projects that

generate positive return on investment. With respect to the first, CDP's climate change program aims to reduce companies' greenhouse gas emissions and mitigate climate change risk. CDP requests information on climate risks and low carbon opportunities from the world's largest companies. Secondly, the water program motivates companies to disclose and reduce their environmental impacts by using the power of investors and companies. With respect to supply chain, in 2016, some 90 organizations, representing over US\$2.5 trillion of purchasing power, requested that their suppliers disclose information on how they are approaching climate and water risks and opportunities. Moreover, CDP collects information from companies through the lens of the four agricultural commodities responsible for most deforestation: timber, palm oil, cattle, and soy. CDP's forest program was first set up by the Global Canopy Programme which remains a prime funder for the program. Finally, CDP Cities provides the global platform for cities to measure, manage, and disclose their environmental data. The potential and need for this program are enormous since soon over half of the world's population will live in cities. CDP Cities provides an easy to use global platform based upon a simple questionnaire that allows city governments to publicly disclose their greenhouse gas emission data.

But, what have motivated firms to disclose according to the CDP? CDP in its website propose that "in recognizing the tangible business benefits of disclosure and action, companies are raising their ambitions and taking meaningful steps to address climate change, deforestation and water security. This ensures their long-term sustainability and profitability, as well as equipping them to respond to regulatory and policy changes, such as the Paris Agreement." Meanwhile, for cities, disclosing environmental data through CDP Cities has a huge number of advantages, from improved engagement to centralizing data and tracking progress.

In more detail, in recent years, we have become aware of the increasing interest in environmental issues leading to a considerable increase in the literature and research carried out internationally

on this topic. As a consequence of the sharp rise in concern with environmental topics, there has recently been an increase in the need to know how companies, governments, and society at large all over the world should confront this problem, which has repercussions at both national and international levels.

Voluntary carbon disclosure could be explained from two theoretical standpoints (Clarkson et al. 2008), which are clearly contradictory in terms of their predictions: (i) sociopolitical theories on legitimization and stakeholders and (ii) economic theory on voluntary information disclosure. From the first perspective, carbon disclosure is seen as one of the strategies used by companies to seek acceptance and approval of their activities from institutional investors (Matisoff et al. 2013), society, or interest groups. Economic theory predicts that this disclosure is influenced by the benefit and risk of the company being affected by third parties.

Adopting this last theoretical argument and based on the capital market transactions hypothesis, firms have incentives to disclose carbon information following CDP as other voluntary information as result of the generation of specific benefits: a reduction in the information asymmetry problems (Lev 1992) and the adverse selection problem wherein informed agents trade on their private information to the disadvantage of uninformed investors (Lang and Lundholm 1996). In addition, companies that opt to disclose information beyond the standard requirements reduce the information risk or increase the investor following, resulting in benefits such as a reduction in capital and debt costs or an increase in the market value of the company (Barry and Brown 1984). Thus, CDP would primarily reduce information asymmetry by assisting investors in evaluating the ethical and environmental practices and their relationship with climate change actions and activities. In addition, it may enhance capital market participants' perceptions of the company from the positive association of being a growth-sustainable organization aware about climate change, a reputation that translates into increased sales.

Moreover, the proactively climate change actions identified by a firm in its carbon disclosure

reports could aid rivals in competing with the disclosing firm. These climate change activities serve as a driving factor in reducing costs, achieving operational efficiency, and improving productivity because they allow the firm to attract better talent and motivate employees (Edmans 2011).

According to Ilinitich et al. (1998), the different stakeholders interested in environmental issues can be consumers, shareholders, potential investors, creditors, regulators, employees, and the general public. Thus, from the consumer point of view, customers are showing a preference for ecological companies and products, and from an investment standpoint, shareholder value suffers when companies pay millions of dollars in fines, cleanup fees, and court costs to keep corporate officers out of jail (Minow and Deal 1991, p. 36).

Within the environmental sphere, companies now have to consider climate aspects as an economic factor in their business strategy, including gathering and reporting and disclosure of greenhouse gas emissions or emission reduction target data, for example (Kolk and Pinkse 2005). According to Freedman and Jaggi (2011), reporting acts as a means to increase transparency, informing stakeholders about corporate actions and strategies related to carbon or greenhouse gas emission accounting. A high degree of carbon information transparency reveals a firm's strategy, which allows interest groups to monitor and seek improvement in the firm's operations (Sroufe 2003; Kolk et al. 2008). However, firms have not been forthcoming about this information in their annual reports since there are no internationally accepted carbon accounting standards that oblige firms to reflect the carbon accounting treatment in their financial accounts, leading it to be considered as voluntary information, thus the need to go deeper into this issue. According to Tang and Luo (2014, p. 89), "carbon accounting collects, summarizes and measures the greenhouse gas emissions data to enable comparisons across reporting periods and facilitate independent reviews for compliance and data accuracy. In addition, sophisticated greenhouse gas emissions accounting can provide executives with real-time visibility into project and firm-level data and account for the financial impact of

emissions, which is increasingly relevant for managerial decisions.”

Despite the efforts made internationally to establish a legal framework to be applied in all countries, currently there are no international regulations within the International Financial Reporting Standards (IFRS) or Generally Accepted Accounting Principles (US-GAAP) that oblige and specify how to disclose carbon accounting in annual reports. In practice, organizations are developing this type of accounting attending to diverse criteria (Hopwood 2009). The impact of the lack of a standardized accounting framework in financial reports is also discussed by Bebbington and Larrinaga-González (2008) and McGready (2008). This divergence in practice undermines the comparability of financial statements, making it harder for stakeholders to make appropriate decisions (Ernst & Young 2009).

Because of these difficulties, companies need to explain their accounting policies to investors and other stakeholders (Ernst & Young 2009) because the purpose behind financial accounting is to provide information to their shareholders and facilitate independent reviews for compliance and data accuracy. Accounting professionals have also expressed concern along this same line, when they point out that “the problem for the accounting profession is there are no accounting standards dealing directly with the carbon accounting treatments yet we must provide a true and fair view of the financial position of the businesses that are impacted by its legislation” (Collier et al. 2011, p. 46).

Since there are as yet no accounting standards that oblige firms in all countries to reflect the carbon accounting treatment in their annual accounts, then this must be considered as information to be disclosed voluntarily. In this context, one of the most prominent initiatives that have emerged for creating a demand for carbon disclosure is the CDP. CDP reflects an international collaboration of institutional investors concerned about the business implications of climate change (Kolk et al. 2008). It is necessary to note that CDP is not a standard-setting organizations; however, its effectiveness in fostering disclosure and

accountability relies on standardized disclosure data. Although information provided in the CDP is voluntary, it is highly structured as it is collected through a questionnaire and reported in a standard tabular format (Depoers et al. 2016). Precisely, at this respect Lyon and Maxwell (2004) suggest that firms proactively perform voluntary environmental agreements for deflecting the enforcement of mandatory regulation, usually more costly.

CDP has built the most comprehensive collection of self-reported environmental data in the world. As Kolk et al. (2008) reported, CDP has been successfully using institutional investors to urge firms to disclose extensive information about their climate change activities. It represents a non-mandatory effort to develop standardized reporting procedures for companies concerning their climate actions. These reports aim to complement financial statements and reporting. Moreover, it also provides information and data and reflects the reality of the business risks and opportunities in hand of a firm. CDP has helped to establish, develop, and perform norms for carbon accounting methodology (Matisoff et al. 2013).

In the context of “win-win” voluntary disclosure, the CDP pursues that carbon disclosure will be an extension of carbon trading in order to build an alliance with environmental groups, companies, investors, customers, and other stakeholders. This is possible because CDP provides and enables a channel for accountability to shareholders and stakeholders that can be used for benchmarking and comparison (Kolk et al. 2008). In the same line, Fiorino (2006) suggests that CDP as initiative of carbon disclosure allows firms to obtain reputational benefits associated to the non-mandatory disclosure of climate change information, carbon trading, greenhouse gas emissions, and so on; moreover, it also decreases and minimizes the risk of pressure exerted by NGOs and other activists for firms that do not disclose this type of information and/or for poorly performing firms in terms of climate change actions and activities. Matisoff et al. (2013) also defend that the convergence in non-mandatory reporting standards and in discourses of CDP participants facilitates and reinforces transparency, comparability, and coordination.

O'Dwyer et al. (2005) also suggest that carbon disclosure represents information that is crucial for the more accurate valuation of assets. Kim and Lyon (2007, p. 5), in this line, suggest that firms' participation in the CDP translates into good news and may positively affect their stock prices around the date of CDP disclosure. However, it is necessary to highlight that voluntary carbon disclosure remains inconsistent and difficult to interpret (Kolk et al. 2008). In this regard, Hassel et al. (2005) pointed out that the efficacy, relevance, and effectiveness of carbon disclosure as voluntary relies on that this information will be relevant and valuable for investors. It must contain information about the financial impact of climate risks and carbon control on the valuation of corporate assets and must avoid that the disclosure generate any doubts about the reliability of the data. For it, CDP exerts a fundamental labor the commensuration of carbon disclosure; it attempts to standardize the reporting of carbon disclosure and aims to decrease the breadth and diversity of activities and the qualitative nature of the data (in contrast to the quantitative nature of financial statements and reports) (Kolk et al. 2008). CDP is also seeking that data will be comparable and reliable for meeting the needs of all stakeholders (investors, customers, suppliers, NGOs, policy makers, governmental bodies, and so on). As Kiernan (2008) noted, these stakeholders demand that information will be complete and consistent between firms and over time.

Advancing the understanding and knowledge of CDP, Sullivan (2009) and, 4 years later, Matisoff et al. (2013) perform a content analysis on CDP from 2003 to 2001 and find that CDP – as its main objective – has demonstrated a higher transparency in later years, especially in Japanese and EU firms. Nonetheless, the transparency and quality of some emissions have not increased over time. At industry level, Matisoff et al. (2013) also find differences attending to the activity sector. At this respect, energy-intensive industries have either increased carbon disclosure and transparency, while less energy-intensive industries have become less transparent; these firms are less incentive and motivated for performing a voluntary carbon disclosure and followed the CDP.

As final point, talking about data that provides CDP in its website, as international organization, it has regional offices and local partners spanning 50 countries. There are now companies, cities, states, and regions from over 90 countries that disclose through CDP. Its network of investors and purchasers, representing over \$100 trillion, along with policy makers around the globe, use its data and insights to make better-informed decisions. Through its offices and partners in 50 countries, CDP has driven unprecedented levels of environmental disclosure.

Moreover, according to the data reported by the CDP, in 2017: Over more than 6300 companies responded to the climate change, water, forest, and supply chain questionnaire; more than 500 cities disclosed environmental information through CDP; CDP's 99 supply chain members represent a combined purchasing power of over \$3 trillion; over 650 investors with US\$87 trillion in assets request information on climate change, water, or forests; and over 100 of the world's states and regions now measure their environmental impacts through CDP. Finally, it is remarkable to highlight that 1/5 of global emissions are now managed through CDP, as reported by companies who represent over half the global market capitalization. Moreover, 827 investors are now requesting data from companies through CDP's climate change program. These investors represent US \$100 tn.

Carbon Emissions

Irmgard Buder

Faculty of Communication and Environment,
Renewable Energy and Electromobility, Rhine-
Waal University of Applied Science, Kamp-
Lintfort, Germany

Synonyms

Carbon dioxide emissions; CO₂-emissions

Definition/Description

Carbon emissions describe the emissions of carbon dioxide (CO₂) by human activities such as the combustion of fossil fuels, steel and cement production, deforestation, and land-use change. The combustion of biofuels is not included in the

inventories of CO₂ emissions of the International Energy Agency (IEA) and the European Union (EU), since it is assumed that this process does not cause net CO₂ emissions (IEA 2016; Janssen-Mahout et al. 2017).

Introduction

Carbon dioxide is a natural component of air. Biological and geological activities release CO₂ which is then absorbed in closed and balanced cycles – the biological and the geological carbon cycle (Sundquist 1985). Additional CO₂ is released by human activities of which the combustion of fossil fuels is the most important (IEA 2016). These emissions are not completely absorbed in carbon sinks as, for example, forests, but either remain in the air or are dissolved in the oceans (University of New Hampshire n.d.). From the industrial revolution onwards, a continuous increase of the global CO₂ content in the air has been observed (NOAA n.d.; Etheridge et al. 1996). This is expected to have severe consequences since the increase of CO₂ in the air leads to an enhanced absorption of infrared (IR) radiation in the atmosphere, which causes a global rise of temperature (see also ► “Greenhouse Gases”, ► “Climate Change”). An increasing amount of CO₂ also leads to increasing dissolution of CO₂ in water. This significantly lowers the pH in oceans and severely affects maritime eco-systems.

Measurement of Global Carbon Dioxide Contents in Air

In 1958, C. D. Keeling started a series of measurements of CO₂ content in the air at a facility of the National Oceanic and Atmospheric Administration (NOAA) at the Mauna Loa Observatory in Hawaii. An increase of CO₂ from 320 ppm in 1958 to 406 ppm at the beginning of 2017 was observed (latest verified measurements) (NOAA n.d.). Other CO₂ measurement sites are operated by the European Union (EU), for example (Ciais et al. 2015).

Preindustrial carbon dioxide levels have been analyzed by measuring the carbon dioxide content of air enclosed in ice cores (Etheridge et al. 1996). “A record of atmospheric CO₂ mixing ratios from 1006 A.D. to 1978 A.D. has been produced. . . The CO₂ data overlap with the record from direct atmospheric measurements for up to 20 years” (Etheridge et al. 1996). The authors determined preindustrial CO₂ levels in a range between 275 and 284 ppm with lower levels during the period of 1550–1800.

The CO₂ content of air can also be measured from space using the infrared spectroscopy of satellites (Butz et al. 2011) which allows a determination of CO₂ and other greenhouse gases (GHG) with a spatial dissolution in the km range (see also ► “Greenhouse Gas Emissions”).

Impact of CO₂ Emissions on Global Climate

CO₂ molecules are able to absorb and emit IR radiation which is why they contribute to the Greenhouse Effect (see also ► “Greenhouse Effect”). Rising amounts of CO₂ in the atmosphere lead to an increased absorption of IR radiation which causes an increase of temperature and climate change (see ► “Climate Change”).

Climate change caused by increasing GHG emissions, including CO₂ which Hansen et al. (Hansen et al. 1981; IPCC 1990) named as the most important among them, has already been identified as a major challenge in the 1980s (IPCC 1990). Reducing the usage of fossil fuels and stopping deforestation are assumed to be key measures in order to reduce the global temperature increase to values below 2.0 °C (UN 2015).

Nevertheless GHG emissions increased from 24.3 Giga tons (Gt) of CO_{2e} in 1970 to 46.6. Gt CO_{2e} in 2012 (Janssens-Maenhout et al. 2017, p. 9). Between 1970 and 2012, CO₂ emissions had the highest share of GHG emissions.

Since CO₂ is the most important GHG, the global warming potential of other greenhouse gases is given as equivalent of the global warming potential of CO₂, carbon dioxide equivalents

(CO_{2e}). The common units are kilograms or metric tons (t) (Krey et al. 2014).

Impact of CO₂ Maritime Eco-Systems

Geological formations and oceans are important sinks of CO₂ (Post et al. 1990). CO₂ is soluble in water and “*Rising atmospheric carbon dioxide (CO₂) concentrations over the past two centuries have led to greater CO₂ uptake by the oceans*” (Feely et al. 2004). Small amount (below 1%) of dissolved CO₂ forms with water carbonic acid (H₂CO₃), which is a weak two protonic acid (Mortimer and Müller 2010).

This means that maritime eco-systems are not only affected by increasing global temperature but also by increasing amounts of dissolved CO₂. Severe impact of CO₂ emissions on the ecology of oceans has already been observed in 2005 (Raven et al. 2005). Raven et al. estimated that in the last 200 years, 50% of the CO₂ emitted by the combustion of fossil fuels and in cement production have been absorbed by the oceans. With the help of surface-ocean CO₂ measurements and existing knowledge of ocean chemistry, they calculated the uptake of CO₂ and found a reduction “*of the pH of surface seawater of 0.1 units, equivalent to a 30% increase in the concentration of hydrogen ions*” (Raven et al. 2005). This finding was in agreement with Jacobson’s estimation that the ocean pH had dropped from 8.25 in historical time to 8.14 in 2004 (Jacobson 2005).

Sources of Carbon Dioxide Emissions

Carbon Dioxide Emissions by Fuel Combustion

The most important source of anthropogenic greenhouse gas emissions is the energy sector with 68% of GHG emissions (IEA 2016, p. 9) (see ► “Greenhouse Gas Emissions”). “*Within the energy sector, CO₂ resulting from the oxidation of carbon in fuels during combustion dominates total GHG emissions*” (IEA 2016, p. 9). According to IEA, CO₂ has a share of 90% of the global GHG emissions in the energy sector.

This is in agreement with Janssens-Maenhout et al., who estimated that in 2012, CO₂ accounted for two thirds of the GHG emissions (Janssens-Maenhout et al. 2017, p. 14) and makes the energy sector the most important sector for GHG reduction measures (see also ► “Climate Change”).

In 2016, 35.8 Gt of CO₂ were emitted worldwide due to the combustion of fossil fuels (Janssens-Maenhout et al. 2017, p. 5; IEA 2016). The amount of CO₂ emissions per energy unit depend on the carbon content of the fuels. Among the different types of coal, anthracite has the highest share of carbon and emits the most CO₂ per energy unit, followed by lignite, subbituminous coal, and bituminous coal. Due to the higher hydrogen to carbon ratio, CO₂ emissions of products made from oil are lower than those made from coal. Natural gas has the highest hydrogen to carbon share and therefore the lowest CO₂ emissions per energy unit.

Table 1 shows the average CO₂ emissions per energy unit for different fossil fuels:

In reporting to the UNFCCC Eq. 1 is used for the calculation of CO₂-emissions.

$$F = EF * AD \quad (1)$$

With F: emission of CO₂, EF: emission factor of the fuel and AD: activity data = amount of energy provided by a certain fuel. (UNFCCC n.d.-a)

The emission factors are defined by the 2006 IPCC Guidelines 2006 (Gómez et al. 2006). Default carbon emission factors are 15.3

Carbon Emissions, Table 1 Carbon dioxide emissions of different fossil fuels

Fuel	CO ₂ in t/TJ
Coal (anthracite)	98
Coal (lignite)	93
Coal (subbituminous)	92
Coal (bituminous)	89
Diesel fuel and heating oil	69
Gasoline	68
Propane	60
Natural gas	50

Data are taken from EIA (n.d.)

tCO₂/TJ for natural gas, 15.7–26.5 tCO₂/TJ for oil products, and 25.8–29.1 tCO₂/TJ for primary coals (IEA 2016).

Carbon Dioxide Emissions by Fuel Combustion Since 1971

In 2014, the highest share of the global CO₂ emissions (28%) was observed in China (incl. Hongkong) (IEA 2016). The second biggest emitter was the USA with a share of 16%. Figure 1 shows the global CO₂ emissions and the CO₂ emissions of the countries, who contribute the most.

Since 1971, the global CO₂ emissions have increased continuously from 1.39 Gt to 20.5 Gt in 1990 and 32.4 Gt in 2014.

As can be seen in Fig. 1 on the left, the USA were the biggest emitter of CO₂ until 2007. Their CO₂ emissions reached a peak between 2000 and 2005, then dropped slightly but still remained on a high level of around 5.2 Gt. In 2007 China took over and became the biggest CO₂ emitter. China's CO₂ emissions increased continuously, leading to a threefold of CO₂ emission from 3.1 Gt to 9.1 Gt between 2000 and 2014.

In Fig. 1 on the right, CO₂ emissions of Germany, India, Russian Federation, and Japan are shown. A continuous increase of CO₂ emissions has been observed for India which overtook Japan, Germany, and the Russian Federation and has now the third biggest emissions of CO₂ with around 2 Gt.

The Russian Federation experienced a sudden decrease of CO₂ emissions in the 1990s, due to a radical shift in the economic system and deindustrialization (IEA 2016). Some further decline was observed between 2013 and 2014.

In Japan CO₂ emissions increased slowly, and in 2014 1.2 Gt of CO₂ were emitted. Only in 2010 as in many countries CO₂ emissions declined due to the financial and economic crisis. Germany's emissions peaked in 1980 (1.0 Gt) and afterwards a continuous decrease was observed – most pronounced in the 1990s. In 2014 0.7 Gt of CO₂ were emitted.

Also of interest are the per capita emissions of CO₂. As can be seen in Table 2, CO₂ emissions per capita vary widely between the discussed countries. The emissions per capita in the table are highest for the USA, even if they declined significantly in the discussed time period. In the Russian Federation and in Germany the emission per capita also decreased but the level still remained high, while in Japan a small increase of CO₂ emissions per capita was observed. A significant increase of CO₂ emission per capita was observed for China and India. Nevertheless, in 2014, the per capita emissions of both countries were much lower than those of the developed countries shown in Table 2.

Kaya Identity

One approach to analyze the CO₂ emissions of the past and to predict future CO₂ emissions either

Carbon Emissions, Fig. 1 Development of CO₂ emission 1970–2014 worldwide and in different countries. (Data taken from IEA (2016))

Carbon Emissions, Table 2 CO₂ emissions per capita in t/capita

Year	World	USA	People's Republic of China	Russian Fed.	Germany	Japan	India
1971	3.71	20.65	0.93		12.49	7.15	0.32
1990	3.88	19.2	1.85	14.59	11.05	8.42	0.61
2014	4.47	16.22	6.66	10.2	8.93	9.35	1.56

Data taken from IEA (2016)

globally or for different countries is the Kaya identity which was first presented in 1991. It states that global carbon dioxide emissions can be expressed as a product of four factors: population, gross domestic product GDP per capita, energy intensity (total energy consumed divided by GDP), and carbon efficiency (carbon dioxide emission per energy unit) (Nakićenović et al. 1998):

$$F = P \times G/P \times E/G \times F/E \quad (2)$$

With F: global CO₂ emissions, P: global population, G: global GDP, E: global primary energy consumption.

An increase in population would lead to an increase of CO₂ emissions since more people need more energy. Economic growth would also lead to an increase of CO₂ emissions since the production of goods needs energy.

A reduction of CO₂ emissions is possible by reducing the energy intensity of production processes, for example, through energy saving measures. The emission of CO₂ can be reduced by increasing the efficiency of carbon, for example, by shifting to less carbon intensive fuels such as natural gas, nuclear energy, or renewable energy (see ► “Energy-renewable”).

Carbon Dioxide Emissions by Sector

In 2014, the sector “Electricity and Heat” held the highest share (42%) of all global CO₂ emissions due to the fact that many countries use coal for electricity production (IEA 2016). “Electricity and Heat” contains heat and electricity production for industry (18%) residential (11%), service (8%), transport (0.5%), and others (5%). As a result of increased power production in Asia,

CO₂ emissions have rapidly increased (IEA 2016, p. 13). At the same time several European countries extended their use of renewable energy in electricity production which has led to a significant decrease of carbon dioxide emissions in electricity production of these countries. In Italy, for example, the share of fossil fuels in electricity production declined from 81% in 2000 to 56% in 2014 (IEA 2016, p. 13).

The second highest emissions were caused by the transport sector (23%), followed by industry (excluding heat and electricity) with 18%, residential (6%), services (3%), and others (7%) (IEA 2016, p. 12).

Other Processes Emitting CO₂ in Industrial Production

Other sources of CO₂ emissions can be found in the industrial production of steel and cement. Besides the high energy demand in the production of iron and steel which mainly uses fossil fuels (Wiley 2011), additional CO₂ is released when iron oxide reacts with carbon to CO₂ and pig iron, iron with a carbon content of 12% (Gallagher and Ingram 2000, p. 202). The processing of pig iron into steel leads to further CO₂ emissions, since the carbon is released as CO₂ (Gallagher and Ingram 2000, pp. 208–209).

Between 1990 and 2018, the amount of steel production increased from around 800 million tons to 1800 million tons (World Steel Association 2019). As a consequence, CO₂ emissions increased proportionally despite various attempts to produce steel more energy-efficiently. According to the World Steel Association “*The steel industry generates between 7% and 9% of direct emissions from the global use of fossil fuel*”

(World Steel Association [n.d.](#)). In industrialized countries, enhanced energy efficiency and improved recycling had led to a significant decrease of CO₂ emission per ton of steel from 3.0 t_{CO2}/t_{steel} in 1980 to 1.82 t_{CO2}/t_{steel} in 1991 (Kundak et al. [2009](#)). Since the industrialized countries have applied all available technical means to reduce emissions by using carbon as reducing agent (Kundak et al. [2009](#)), a further reduction of CO₂ emissions can only be achieved by either using carbon capture (Wiley et al. [2011](#)) or by replacing carbon by hydrogen (Kundak et al. [2009](#)). A demo-plant in Sweden which uses hydrogen that is generated by electrolysis (Karagiannopoulos [2018](#)) is supposed to start operation in 2020. It will use electricity produced from hydropower for the production of “green” steel.

In cement production, around 50% of the CO₂ emissions are caused by the combustion of fossil fuels. The other 50% are released during the calcination of limestone, which reacts with silicates to form calcium oxide, the main component of clinker (Worrel et al. [2001](#)). Limestone mainly consists of calcium carbonate CaCO₃. When heated in the kiln to 600–900 °C, CaCO₃ decomposes to form calcium oxide CaO and CO₂ (Gibbs et al. [n.d.](#)). While the carbon intensity of the fossil fuel can be reduced by shifting to less carbon intensive energy forms, the release of CO₂ during the process of calcination is much harder to reduce (Worrel et al. [2001](#)). One option would be to substitute parts of the clinker “*by industrial by-products, such as coal fly ash (a residue from coal burning), blast furnace slag (a residue from ironmaking), or other pozzolanic materials (e.g., volcanic material)*” (Worrel et al. [2001](#)). Replacing clinker by other materials would change the properties of the resulting concrete, so more systematic investigation is required.

In sum, the contribution of the cement industry to the global anthropogenic CO₂ emissions at begin of the 2000th was about 5% (Worrel et al. [2001](#)). In 2016, the global cement production released 1.45 Gt ± 0.2 Gt of CO₂, which is around 4% of the emissions of fossil fuels (Andrew [2018](#)).

Carbon Dioxide Emissions by Land Use Change

Further carbon dioxide is released by deforestation, drying of wetlands and other land-use changes. In the IPCC GHG inventory, anthropogenic land use and land cover changes (LULCC) describe GHG emissions of human activities (UNFCCC [n.d.-b](#)). These processes also diminished the ability of terrestrial biosphere to absorb carbon dioxide. It is estimated that around 20% of the fossil fuel CO₂ emissions are absorbed by terrestrial biosphere, soil, and vegetation (Arneth et al. [2017](#)). The ability of land to absorb CO₂ depends on its use.

While it is well known that CO₂ is absorbed by vegetation via photosynthesis, the carbon uptake of soil has mostly been investigated with a focus on the quality of the soil and the productivity in agriculture and forestry (Powlson et al. [2004](#)). Only in recent years, at the beginning of 2000, the importance of soil as a carbon sink has come into focus (Powlson et al. [2004](#); Schlesinger and Andrews [2000](#)). Wood harvesting, grazing, and crop harvesting as well as crop land management lead to a reduction of soil carbon pools which are difficult to quantify but also contribute to LULCC (Arneth et al. [2017](#)). On the other hand, afforestation could lead to an absorption of carbon dioxide and in the long term to an increase of the carbon content of the soil (Kudeyarov [2018](#)).

Accounting is also difficult due to different time scales of the different processes: Deforestation leads to a rapid carbon loss, whereas it is lost slowly in the post-deforestation phase. The uptake of carbon in areas of regrowth also occurs slowly (Arneth et al. [2017](#)).

Dynamic global vegetation models are used to describe the magnitude and spatial distribution of GHG and CO₂ emissions (Arneth et al. [2017](#)). Since the typical resolution of the models is in the range of over thousands of kilometers squared, subgrid changes, which can have significant effects on the simulated carbon cycles, are not considered (Arneth et al. [2017](#)). This leads to high uncertainties in regard to the estimations of carbon emissions due to LULCC. For the time period of 1901–2014, Arneth et al. estimated

that by land use change cumulated 35 ± 18 GT carbon (equal to 128 ± 66 Gt CO₂) were emitted.

Measures for Carbon Dioxide Emission Reduction

There are different strategies to reduce CO₂ emissions. In 2015, a worldwide agreement was achieved, stating that the temperature change should be kept below 2 °C and that actions which help to keep the temperature increase below 1.5 °C should be taken (UNFCCC 2015).

Different types of targets concerning a reduction of GHG emissions were formulated which included fixed level targets, targets relative to business as usual, trajectory targets, and non-GHG emission targets such as shift to renewable energy, increasing energy efficiency, afforestation, and mitigation targets (Vaidyula and Hood 2018).

In order to reduce CO₂ emissions, also carbon sequestration is discussed (Hu et al. 2016). But technical and economical feasibility for large scale carbon capture has yet to be shown (Aminu et al. 2017).

Summary

Increasing CO₂ emissions within the last 200 years have led to a significant increase of CO₂ in the atmosphere from below 300 ppm in preindustrialized time to above 400 ppm in 2017 (NOAA n.d.). Since CO₂ emissions absorb IR-light, the energy balance of the earth has shifted. An increase of around 1 °C due to increased CO₂ and other GHG emissions has been observed within the last 100 years (Lindsey and Dahlmann 2018). In order to limit the temperature increase to values below 2 °C GHG emissions shall be reduced (UN 2015). CO₂ is the most important GHG, since CO₂ emissions from the combustion of fossil fuels are dominant, most important in the energy sector (IEA 2016). Increasing energy demand especially in the developed countries led to a continuous increase of CO₂ emissions globally. Nevertheless mean per capita

CO₂ emissions are much lower in developing countries than in developed countries (IEA 2016). In recent years, some European countries have been successful in reducing CO₂ emissions, for example, by shifting to renewable energy.

Synonyms

Global warming potential

Definition

The term *carbon footprint* (CF) refers to the measurement of direct and indirect net climate change impacts of a product, process, company, or system. The sole impact category of the CF is climate change, typically expressed as global warming potential (GWP) impacts caused by greenhouse gas emissions. The standard unit of measurement for GWP impacts is carbon dioxide equivalent, which is based on the global warming potential including lifetime of different greenhouse gases in the atmosphere. A carbon footprint may be evaluated through life cycle assessment methodology, including all relevant life cycle stages of the system under study. CF assist different actors in mitigating their climate change impacts and in identifying more climate friendly options. The CF concept is widely utilized both in science and business because it is readily understandable, making it an important tool in bridging the gap between the scientific community and decision makers.

Introduction/History

Climate change is a major challenge to sustainability for humankind and it has been accelerating,

especially due to anthropogenic greenhouse gas emissions. After meetings in 1988, 1995, 2001, and 2007, the Intergovernmental Panel on Climate Change (IPCC) published assessment reports on climate change and the role of greenhouse gases (IPCC 2000). In 1998, the Kyoto Protocol defined global warming potential (GWP) impacts for major greenhouse gases (GHG) (United Nations 1998). The measurement of GHG emissions and their impacts has become essential to understanding the reasons behind climate change and to devising strategies to reduce these impacts. According to Caro (2019), the carbon footprint is a relatively easy-to-use tool for monitoring and quantifying greenhouse gas emissions and associated impacts. The advantages of the CF tool are that it includes both direct and indirect impacts from different life cycle stages. The CF has become the most popular indicator in sustainability assessments because it can be utilized across a wide range of applications: products, processes, companies, and countries.

Because of increased interest in and awareness of climate change in previous decades, a new and easily applied tool to measure climate change impacts was required. This led to the process of developing the CF. The origin of the carbon footprint derives from the ecological footprint. Wackernagel and Rees (1996) presented the ecological footprint to describe human impacts on Earth. At first, the ecological footprint was related to the land area required to sustain various human activities (Monfreda et al. 2004; Huijbregts et al. 2008). According to Monfreda et al. (2004), the ecological footprint generally presents “how much land area . . . the human economy need [s] to provide ecological goods and services it uses at a renewable rate.” The first definition for the CF was also based on land (Wiedmann 2009). According to De Benedetto and Klemeš (2009), the CF stood for the land area required to sequester fossil-based CO₂ emissions from the atmosphere through afforestation. This calculation required a detailed input-output analysis (Wiedmann 2009).

However, there was no clear definition for the term *carbon footprint* until Wiedmann and Minx (2008) amassed previous definitions and proposed

that “The carbon footprint is a measure of the exclusive total amount of carbon dioxide (CO₂) emissions that is directly and indirectly caused by an activity or is accumulated over the life stages of a product.” This led to the current definition, in which a carbon footprint measures greenhouse gas emissions or their impacts (rather than land area for carbon sequestration purposes).

The term CF in general became more popular in the 2000s, and at that time, a key question in the scientific literature was the extent to which CO₂ emissions could be attributed to a certain product, process, company, or organization. Businesses had a particular interest in using the carbon footprint indicator; as Lash and Wellington (2007) pointed out, a reduced carbon footprint might provide business advantages for companies. According to Weidema et al. (2008), proactive companies and retail chains have been notable in spreading CF thinking throughout society. Non-governmental organizations (NGOs) were also key promoters in the early years of the CF. Unlike business and NGOs, academic research was not a driving force in the development of the carbon footprint tool, and this contributed to the emergence of different definitions and calculation methods (Weidema et al. 2008).

Wiedmann and Minx (2008) observed that many CF calculations included other greenhouse gases in addition to carbon dioxide. This quickly led to all CF calculations generally including other greenhouse gases. The CF evolved to quantify GHG emissions contributing to global warming and climate change, and indicators such as the global warming potential began to be used widely (Čuček et al. 2012). Also, other terms, such as *climate footprint*, *CO₂ footprint*, *GHG footprint*, *methane footprint*, and *GWP footprint*, were suggested by different researchers (Čuček et al. 2012). CF applications also expanded, for example, to products, processes, companies, and nations (Hertwich and Peters 2009). At this point in time, the popularity of the definition based on land area waned (Alvarez et al. 2016). According to the International Reference Life Cycle Data System (ILCD) Handbook, LCAs should also include other impact categories besides the carbon footprint, except in cases in which the GWP is the

major environmental sustainability impact (European Commission et al. 2010).

According to Muthu (2014) and Alvarez et al. (2016), the carbon footprint has become a globally accepted and widely implemented tool or indicator for quantifying greenhouse gas emissions of products. However, the enormous interest in the CF concept and lack of consensus in calculation methodologies have also led to public hesitation and confusion (Alvarez et al. 2016). The standardization of the term *carbon footprint* as well as the calculation methods and rules outlined in documents such as Publicly Available Specification (PAS) 2050 (2008 and 2011), the Greenhouse Gas Protocol (2011), International Organization for Standardization (ISO) 14067 (2013), and ISO 14067 (2018) have clarified the topic and enabled more uniform assessments.

Standardization

The International Organization for Standardization has published ISO 14040 and 14044 international standards to provide guidelines for LCA studies. The ISO 14040 standard addresses principles and framework for life cycle assessment methodology. Its main scope is to provide rules for conducting LCA studies. The ISO 14044 standard supplies additional information for LCA studies, including, for instance, goal setting, inventory analysis, impact analysis, results analysis, reporting, critical review, and limitations.

Publicly Available Specification of the British Standard Institution (BSI), PAS 2050 aims to present a consistent method for GHG emission assessment of goods and services throughout the life cycle. PAS 2050 is based on the ISO 14040 and ISO 14044 standards (BSI 2011). It provides instructions for GWP assessment, system boundaries, data quality, and allocation procedures. However, PAS 2050 does not use the term *carbon footprint*.

The Greenhouse Gas Protocol (2011) used PAS 2050 as a base when developing its own product standard. The Greenhouse Gas Protocol (2011) presents the CF as a subcategory of life cycle assessment (LCA) because it only focuses

on the climate change impact category. This protocol takes an attributional approach, whereby GHG emissions and removals are attributed to the functional unit linking together attributable processes along its life cycle. The attributional approach typically uses primary data or average data for a given process (Greenhouse Gas Protocol 2011).

The Greenhouse Gas Protocol presents three “scopes” for greenhouse gas emissions assessments for companies. Scope 1 includes direct greenhouse gas emissions from sources that are owned or controlled by the company. Scope 2 includes GHG emissions from the production of purchased electricity consumed by the company. Scope 3 is an optional category which includes all other indirect emissions (i.e., those which are a consequence of the operation of the company, but which are released in processes not owned or controlled by the company) (Greenhouse Gas Protocol 2004).

Product carbon footprint assessment was first standardized by the ISO 14067 standard in 2013 and was updated in 2018. The update (ISO 14067: 2018) specifies principles, requirements, and guidelines for measuring and reporting the CF of a product. The CF assessment is presented so that it is consistent with the aforementioned ISO 14040 and 14044 standards, which provide general guidelines for LCA. ISO 14067: 2018 only addresses the climate change impact category, and it does not include carbon offsetting. According to the standard, the CF of a product is the net greenhouse gas emissions in a life cycle of a product system presented as CO₂ equivalents, using the impact category of climate change. CO₂ equivalent results should be presented as mass per functional unit. GHGs can be attributable to natural or anthropogenic sources, and they absorb and emit infrared radiation from the Earth’s surface, atmosphere, and clouds at specific wavelengths. The standard focuses on long-lived GHGs; therefore, short-lived radiative forcing agents and surface reflectors such as black carbon and aerosols also fall outside the scope. Water vapor and ozone are also outside the scope of the standard.

In addition to a single product, a partial CF can be calculated for a product, or for a system

including two or more products of the same organization. The ISO 14067 standard is the first of its kind to offer a detailed guide and standardized template for an external communication report for the CF, tracking report, declaration, and label. This facilitates more transparent communication and comparisons for CFs. The ISO 14064 standard also describes specifications and guidance for greenhouse gas emission quantification, monitoring, reporting, and verification at the organizational level (ISO 14064-1), project level (ISO 14064-2), and product level (ISO 14064-3).

Key Issues

According to the current standardization guidelines, a carbon footprint should be presented as CO₂ equivalents in mass units related to global warming. This requires global warming potential factors for other greenhouse gases in relation to CO₂. The GWPs of different greenhouse gases have been measured based on their impacts on radiative force over a given time horizon. Typical time horizons are 20 and 100 years, but in CF assessment, 100 years is most often used. For a 20-year assessment, the GWP impacts of methane (CH₄) become more significant due to the short lifetime of methane in the atmosphere.

IPCC (2007) defines and publishes global warming potentials for 61 different greenhouse gases. CO₂, CH₄ and nitrous oxide (N₂O) are typical greenhouse gases that can be released from natural or anthropogenic processes. The main sources of CO₂ are related to the combustion of fossil fuels. CH₄ and N₂O are released from energy production, but also from agricultural processes, for example. In addition, there are multiple other greenhouse gases, such as fluorinated gases. Fluorinated gases are synthetic, and they are emitted from industrial processes. They typically have considerable GWP impact factors, but their quantities are rather low (EPA 2017).

According to Gasser et al. (2017), one of the challenges in defining the GWP factors of other greenhouse gases in relation to CO₂ is the climate-carbon feedback. CO₂ emissions increase the CO₂ pool in the atmosphere. Part of this CO₂ is absorbed by sinks. However, due to the warming climate, the CO₂ uptake from atmosphere slows down, impacting the CO₂ lifetime in the atmosphere (Gasser et al. (2017).

Table 1 presents the GWP impact factors for some of the typical greenhouse gases according to the IPCC's 5th assessment report and IPCC (2007).

Figure 1 presents the core idea of a carbon footprint calculation. The GHG emissions from different life cycle stages are calculated as CO₂

Carbon Footprint, Table 1 The global warming potentials of example greenhouse gases over 20- and 100-year time horizons with and without climate-carbon feedback (cc fb) (Myhre et al. 2013; IPCC 2007)

Greenhouse gas	Lifetime (a)		GWP ₂₀		GWP ₁₀₀	
	Myhre et al. 2013	IPCC 2007	Myhre et al. 2013	IPCC 2007	Myhre et al. 2013	IPCC 2007
CO ₂				1		1

Carbon Footprint, Fig. 1 Carbon footprint calculation

equivalents using GWP factors for different gases. The CF calculations only include climate change impacts; other impact categories are excluded. The goal and scope define whether the CF is calculated for a product, service, or company and what is a functional unit of assessment. Included life cycle steps are presented, and a study may be related to full or partial product life cycles (e.g., cradle-to-gate, cradle-to-grave, or gate-to-gate).

Future Directions

The definition of carbon footprint has evolved over time, and multiple methodological issues related to CF assessment have arisen. One of the main challenges of the CF concept pointed out by researchers is the methodological divergence between product carbon footprints and corporate ones. It is difficult to compare CFs resulting from the application of different methods, and this may weaken consumer confidence in the reliability of the carbon footprint information (Alvarez et al. 2016). The ISO 16047 standard diminishes the methodological and terminological confusion. Notwithstanding this, due to the popularity of CF and possible public misperception, further development of the CF tool is necessary.

According to Caro (2019), the utilization of the CF at the micro level, e.g., product level, has received an international reputation, but at the macro level, e.g., global level, the international community has not strongly approved its application, so methodological development is still clearly required.

Many carbon footprint labels have been developed in order to interface with consumers (Ecolabel index 2019). However, different methodologies and ways of presenting a carbon footprint exist. This may further confuse consumers, especially if the CF labels are not comparable. Therefore, more uniform carbon footprint labeling is also essential in the future.

Previously, countries reported their carbon footprint with production-based or area-based boundaries. According to Caro (2019), carbon leakage and embodied emissions in international trade may be revealed in the country-level CFs, if an approach based on consumption is used. This might have significant impacts on the global trading system in the future (Caro 2019). This type of approach has attracted more interest because it also includes emissions related to a country’s consumption in terms of material, product, and energy production not only within the country but also externally, throughout the globe.

As a carbon footprint is a reflection of the negative climate impacts of products and companies, calls have been made for quantifying and communicating the positive climate impacts as well. The carbon handprint approach (Grönman et al. 2019) has subsequently been proposed. This approach is built largely upon standardized CF methodology, but complements it by offering guidelines for setting up a comparison between the baseline solution and the handprint solution, which presumably contains climate benefits.

Summary

The carbon footprint has become one of the most commonly used indicators of environmental sustainability assessment. It presents direct and indirect global warming potential impacts of a product, process, system, company, or country. The carbon footprint is presented in mass units as CO₂ equivalents by using the global warming potential impact factors of different greenhouse gases. Previously, carbon footprint calculation rules varied greatly, but the International Organization for Standardization has standardized them in the ISO 14067 standard (2013 and 2018).

Greenhouse Gas Footprint or Climate Footprint

Definition

Carbon footprints have been designed and promoted by nongovernmental organizations, companies, and different private organizations that have climate change in the spotlight. Historically, it has been associated with emission sources, without paying excessive attention to emission drivers (Peters 2010); among emission drivers, we can identify firms, organizations, households, existing infrastructures, production systems, or government policies and nations.

Introduction

Over last years, firms are aimed to diminish emissions from their business activities, and invest in low-emissions products and technologies (Kolk et al. 2008). Moreover, organizations are seeking to develop “organizational and informational infrastructures for assessing, measuring, reporting and managing greenhouse gas emissions and their associated impacts” (Kolk et al. 2008, p. 720). Climate change and the reduction of the carbon emissions are one of the main environmental concerns of communities, organizations, firms, policymakers, governments, and so on (Weidema et al. 2008). In this context, the United Nations, the European Union, and a large list of countries have established regulation and planned tools with the purpose of reducing the carbon emissions (Hua et al. 2011). Their objective was to reduce and alleviate global warming.

In general, and as Wiedmann and Minx (2008) pointed out, the agenda of organizations, investors, politicians and society has seen an increase in both issues and concerns about climate change, demanding greater attention regarding the carbon footprint. It is necessary that companies begin to include its management into their corporate choices for reducing global warming and, more specifically, carbon emissions (Hua et al. 2011). Precisely, among the reasons for being carbon footprint it is in the interest caused by household environmental and integrated product policy (Hertwich 2005; Lenzen and Foran 2001). Hertwich (2005) pointed out that activities

causing GHG emissions help humans by providing consumer goods and services. Lenzen et al. (2001), meanwhile, for an Australian study defended the need of a responsible water use because of its consumption activities and the life-style gleaned therefrom. It must be not valid to apportion the environmental damage from inappropriate water use.

This term has undergone a remarkable evolution in recent years which particularly stands out in the UK (Weidema et al. 2008). Carbon footprints have been planned and promoted by non-governmental organizations, companies, and different private organizations that have climate change in the spotlight. Historically, it has been associated with emission sources, without paying excessive attention to emission drivers (Peters 2010); among emission drivers, we can identify firms, organizations, households, existing infrastructures, production systems, or government policies and nations.

However, despite its growing importance and relevance within the academy, to date no common definition of carbon footprint has been found. It generates and leads to a notable confusion about that term. Numerous are the explanations about its concept and numerous are the approaches adopted in the definitions, but there is no single definition that is homogeneous and unanimous in the literature. Wiedmann and Minx (2008) collect in their study some of these definitions that provide the basic ideas about what carbon footprint is, and what we understand by carbon footprint that we synthesize in the following:

- For BP (2007), “the carbon footprint is the amount of carbon dioxide emitted due to your daily activities – from washing a load of laundry to driving a carload of kids to school.”
- Patel (2006) pointed out that for the British Sky Broadcasting (SKY), they are measured as “the CO₂ equivalent emissions from its premises, company-owned vehicles, business travel and waste to landfill.”
- The Carbon Trust (2007) pointed out “... a methodology to estimate the total emission of greenhouse gases (GHG) in carbon equivalents from a product across its life cycle from the production of raw material used in its manufacture, to disposal of the finished product (excluding in-use emissions)”; and “... a technique for identifying and measuring the individual greenhouse gas emissions from each activity within a supply chain process step and the framework for attributing these to each output product (we [The Carbon Trust] will refer to this as the product’s ‘carbon footprint’)” (Carbon Trust 2007, p. 4).
- For ETAP (2007) “...the ‘Carbon Footprint’ is a measure of the impact human activities have on the environment in terms of the amount of greenhouse gases produced, measured in tonnes of carbon dioxide.”
- Meanwhile, the Global Footprint Network (GFN) in 2007 defines carbon footprints highlighting “the demand on biocapacity required to sequester (through photosynthesis) the carbon dioxide (CO₂) emissions from fossil fuel combustion” (GFN 2007).
- Grubb and Ellis (2007) clearly pointed out that “a carbon footprint is a measure of the amount of carbon dioxide emitted through the combustion of fossil fuels. In the case of a business organization, it is the amount of CO₂ emitted either directly or indirectly as a result of its everyday operations. It also might reflect the fossil energy represented in a product or commodity reaching market.”
- Peters (2010, p. 245) defines them as “all emissions of a product both backward in time from the point of consumption to emissions sources and forward in time to include the use and disposal phase of products” and “carbon footprint may be too restrictive as climate is affected by more than carbon (e.g., N₂O, SO₂, black carbon, land use change, albedo, and so on).”
- For the Paliamentary Office of Science and Technology (2006), “a ‘carbon footprint’ is the total amount of CO₂ and other greenhouse gases, emitted over the full life cycle of a process or product.”
- Lash and Wellington (2007) and Hertwich and Peters (2009) consider that the term also represents the interest of several agents like industries, consumers, suppliers, regulatory bodies,

and so on. Hertwich and Peters (2009, p. 6414) define the term “as the greenhouse gases CO₂, methane, nitrous oxide and fluoride emitted in the production of goods and services used for final consumption and greenhouse gases emissions occurring during the consumption activities themselves.”

- Following the Carbon Trust (2009), for Hua et al. (2011, p. 179), “carbon footprint measures the total greenhouse gas emissions caused directly and indirectly by a person, organization, event or product in tonnes (The accounting profession normally avoids any type of conversion and tries to express each phenomenon to the most appropriate extent (Stahmer 2000). In this regard and regarding the measure of carbon footprint, Wiedmann and Minx (2008) choose to express and measure the carbon footprints in tonnes of carbon dioxide, with this measure they try to avoid the use of type of conversion.) (or kg) of CO₂ equivalent.”

From the above, Wiedmann and Minx (2008, p. 4) being aware of the previous definitions clarify the definition as follows: “carbon footprint is a measure of exclusive total amount of carbon dioxide emissions that is directly and indirectly caused by an activity or is accumulated over the life stages of a product.” Examining in detail the definition, these authors include as carbon footprint all the activities of the different agents (populations, governments, businesses, organizations, activity sectors, and so on, and even products refer to good and services). Moreover, they stated that for calculating carbon footprint direct and indirect emissions must be considered. It must be noted that direct emissions refer to on-site and internal emissions while indirect emissions refer to off-site, external, embodied, upstream, and downstream emissions.

As Peters (2010) pointed out, there is not an extensively recognized term of carbon footprint. Nonetheless, once we have covered its definition, it also is necessary to point out the following steps for organizations, consumers, governments, policymakers, and so on for decreasing carbon emissions. As Carbon Trust (2006, p. 4) included

in its reports, “managing the carbon footprint of products across the supply chain is the next step for business to take in the effort to reduce carbon emissions and mitigate climate change. There are several issues driving business to take action, including: (i) increases in direct energy costs and the energy costs of suppliers; (ii) existing and planned legislation which penalises high energy consumption and rewards emissions reductions; and (iii) changing consumer attitudes to climate change, presenting forward-thinking companies with an opportunity to develop and market low-carbon products.”

In this respect, Carbon Trust (2006, p. 6) also suggest the existence of three steps that any organization can take to decrease the carbon footprint and thus slow down climate change. In the following and attending to the report of this organization, the three stages are described.

The first step focuses efforts on decreasing direct emissions. The proposed actions are:

- “Implementing all cost-effective energy efficiency measures, such as heating and lighting upgrades, using new process technologies and delivering staff training and awareness programs.
- Developing low-carbon energy sources such as on-site generation.
- Addressing the more strategic business risks and opportunities associated with climate change. Typically, this can include work on regulatory compliance, value at risk, future cost of carbon, other market risks and opportunities, and shareholder and other stakeholder impacts.”

As Carbon Trust (2006) highlights, there are several associated benefits of doing this. Among them, cost savings stand out as the organization reduces the cost of its energy bills. Also, there is the improvement of operational efficiency and its reputation. And finally, the reduction of regulatory risks also stands out.

The second step focuses on decreasing indirect emissions by working with organizations via the supply chain. Through the supply chain, the amount of carbon footprint can be calculated

since the total quantity of raw materials and all the necessary processes are considered until the final good/service is on the market. Knowing these data allows us to identify those sections of the supply chain where efforts must be intensified to reduce emissions and energy costs. Furthermore, it should not be forgotten that this approach allows companies to adapt to changes in consumer demands, being able to develop products adapted to low carbon emissions that have a positive impact on their market value and corporate performance.

Step 3 is elective and is focused on offsetting. Carbon Trust (2006) considers carbon offprint as the possibility of offsetting the carbon emissions of one company with others. This is materialized through credits related to the reduction of emissions of carbon dioxide or other greenhouse gases. This initiative may be interesting for those companies more oriented to the consumer or the service sector due to the benefits associated with action against climate change. Of course, to guarantee the success of the carbon offprint it is essential that the credits that are acquired are correlated with verified projects and really linked to emission reductions.

In the first step, the abovementioned direct emissions are analyzed considering a wide variety of business actions, which also includes a set of products designed and provided by the Carbon Trust. In addition, several companies have also chosen to develop strategies that allow them to compensate for excess emissions; they buy credits associated with reducing gas emissions (third step). It should be noted that to achieve the reduction imposed by the UK, much deeper cuts are required than what is proposed at this stage, so every organization should also consider the opportunity to reduce the carbon footprint related to the second step.

Referring again to the Carbon Trust (2006) report, in page 9 this organization pointed out that “the methodology developed draws heavily on standard life-cycle analysis techniques (LCA).” The United Nations Environment Program (UNEP) describes LCA as “. . .the process

of evaluating the effects that a product has on the environment over the entire period of its life cycle. . . extraction and processing; manufacture; transport and distribution; use, re-use and maintenance; recycling and final disposal.” Moreover, the methodology to calculate carbon footprints could be described in four stages. The first stage refers to the initial scrutiny; the second stage to its construction; the third stage to identify opportunities and establish the order of priority between them; and the last stage to the development of the plan once the results of the previous phases have been presented.

But the debate is not only about what the carbon footprint is, but also how this footprint carbon is to be measured. Wiedmann and Minx (2008) precisely question whether carbon footprint must contain CO₂ emissions, other greenhouse gas emissions, or even additional constituents that do not contain carbon in their molecule. Carbon footprints are valuable for promoting and implementing more active policies for decreasing climate change (Matthews et al. 2008). In any case, the data and nature of the information of the carbon footprint will be contingent on how it was measured, then multiple possibilities exist. Weidema et al. (2008) was also aware of the diversity of possibilities to quantify and present carbon emissions data in a consistent manner. Among the range of possibilities, Weidemann and Minx (2008) point out that they could be measured from two methodological approaches. The first of them refers to the bottom up and is based on a process analysis (PA). The second one refers to the top down and is based on environmental input-output (EIO). In spite of the differences that will later be signaled between both approaches, both are aimed at capturing the full life cycle. Peters (2010), at this respect, suggest that the method used to measure carbon footprint depends on the type of products. Consumer products usually use bottom-up LC. But, other studies usually employ the top-down input-output analysis (Wiedmann 2009) especially when they focus at country level. But also, as Weidemann and Minx (2008) suggest, the selection of the

approach also is contingent to the accessibility of data and the purpose of the enquiry.

PA is the bottom-up approach, developed with the aim of reinforcing the understanding of the environmental effect that individual products have from the beginning to the end of their days (Wiedmann and Minx 2008). At this respect, Lenzen and Foran (2001) pointed out that the bottom-up nature of PA-LCAs reflects a system boundary problem only on-site. When this approach is adopted to calculate and capture the carbon footprint, special care should be paid to the identification of system boundaries. It should be noted, however, as Tukker and Jansen (2006) and Wiedmann and Minx (2008, p. 5) suggest, that the adoption of this approach requires that “a subset of individual products be representative for a larger product grouping and the use of information from different databases.”

For its part, the EOI approach has a top-down orientation to compute carbon footprint. Under this method, information is provided on all organizations at the sector level. Considering that the environmental data will be robust, under this approach of top-down EOI, the carbon footprints could be estimated by employing a more inclusive and strong technique. As in the previous approach, it is necessary to set the entire economic system as a boundary line (Wiedmann and Minx 2008). As a disadvantage, this method also requires that – at sector level – the product (good/service) be restricted, and that there be homogeneity in prices, outputs, and carbon emissions. Nonetheless, its main benefit is the shorter time and manpower (Wiedmann and Minx 2008).

The best possible approach would be the combination in a hybrid of both methods, thus combining the strengths of each of them and minimizing their disadvantages (Suh et al. 2004; Heijungs and Suh 2013). This fusion would consider preserving the detail and accuracy of the PA approach while covering the high-order requirements of the EOI approach.

Finally, the process of standardization of a unique and valid measure of carbon footprint

is one of the manifestations that firms, organizations, households, governments, and so on are beginning to diminish carbon footprint and take into account in their business decisions (Peters 2010). Many of these agents are increasing their concerns about climate change and carbon emissions, designing and promoting so several projects to reduce the global climate change (as carbon footprint). Global carbon emissions regulation is imminent (Matthews et al. 2008). At this respect and as final remark, in the development of valid and generalizable measures of carbon footprint the international trade should be included; the unanimous measure must include a more comprehensive approach for carbon footprint estimation.

Definition/Description

A carbon handprint is a new approach developed to quantify the positive climate impact of products and services. In contrast to carbon footprint, which refers to negative global warming potential as a consequence of greenhouse gas (GHG) emissions over the life cycle of a product, a carbon handprint indicates the reduced amount of greenhouse gas emissions due to the use of a specific product or a service. A carbon handprint can be thus defined as *the beneficial climate impact that organizations can achieve and communicate by providing products or services that reduce the carbon footprints of customers* (Grönman et al. 2019).

Carbon handprint builds upon the assumption that reducing the product’s carbon footprint alone is not a handprint. Carbon handprint can be achieved in a provider–customer relationship, when the provided goods, intermediate product, raw material, service, technology, etc. (hereafter: a product), that a customer uses, serves to reduce the customer’s carbon footprint when compared to a baseline practice. A carbon handprint, therefore, is always a carbon footprint calculation of the modified situation against the baseline situation: see Fig. 1. Carbon handprint can be used in the communicating and marketing of global warming reduction potential as well as in identifying the development needs of a product.

Development of the Handprint Concept

The term ‘handprint’ was first introduced in 2007 by UNESCO and determined as a measure of Education for Sustainable Development action, aiming to decrease the human footprint (Hand

Carbon Handprint, Fig. 1 Carbon handprint (CH) is the difference of carbon footprints (CF) of the baseline solution and the handprint solution when a customer is using either the baseline product or the handprint product

Print Action Toward Sustainability [n.d.](#)). Shifting handprints to serve as environmental indicators is based on the work done by Biemer et al. (2013) and Norris (2015). Grönman et al. (2019) introduced the definition (see above) and calculation guidelines specifically for carbon handprint assessments. Norris (2019) backs up the Grönman et al. definition by determining handprints as *reductions in footprint related impacts outside the scope of the actor's footprint with respect to business as usual*. Most recently, Kühnen et al. (2019) introduced a handprint methodology that focuses on positive contributions to sustainable development.

The need for carbon handprint quantification and communication has risen from the industrial sector. Many companies and organizations already act responsibly toward the environment, so they might have already minimized their resource use as well as the emissions and waste

created. They could even be providing products or services that help their customers reduce their environmental impact. However, these frontrunner companies have also been forced to settle for using traditional life cycle assessment (LCA) quantifying their negative environmental impacts. Besides handprints, other concepts or indicators for environmental benefits have emerged, e.g. Cradle to Cradle (McDonough and Braungart 2002), unburdening of the environment (Kravanja and Čuček 2013), positive footprints (Dyllick and Muff 2016), and net positivity (Dyllick and Rost 2017; Norris 2015).

The goal for carbon footprints is to see a reduction close to zero whereas, with handprints, there is no upper limit on the positive impacts that can be achieved (Biemer et al. 2013). Some studies have used a negative footprint to illustrate the positive impact, which has led to confusion regarding the footprint concept. These starting

points indicate a clear need for developing a scientifically sound calculation approach for carbon handprint that organizations can use effectively.

Carbon Handprint Calculation Process

The carbon handprint approach of Grönman et al. (2019), which is further presented in Pajula et al. (2018) and Vatanen et al. (2018), is based on ISO standards for life cycle assessment (ISO 14040 2006 & ISO 14044 2006) and for carbon footprint (ISO 14067 2018). The carbon handprint approach complements these standards by offering guidance in setting up a comparison between the handprint solution and baseline solution:

especially by identifying customers of the product, identifying potential carbon handprint contributors, and defining the baseline. Figure 2 illustrates the four stages and ten steps in the carbon handprint approach, which are then described in more detail.

Stage 1: Identification of the Operation Environment

In the first stage, the conditions of the product’s operational environment are identified. This stage forms the core of the carbon handprint assessment and is additional to traditional LCA. As the first step, the (potential) user of the product, or the customer, is recognized. Because carbon handprint is always calculated in the

Carbon Handprint, Fig. 2 The carbon handprint calculation process (Pajula et al. 2018)

provider–customer interface, it is essential to define who the customers are and where and how they are using the product. Different kinds of customers using the product differently or in different operating environments can also be identified.

Next, a hypothesis is formed on the mechanism, in terms of how this product can reduce the carbon footprint of the customer using it. This hypothesis affects in following steps, defining the baseline and the system boundaries. Whether the carbon handprint outperforms the baseline product in this regard will be verified

while conducting the carbon footprint calculations. Examples of possible contributing mechanisms for carbon handprint creation can be seen in Fig. 3.

As a third step, the baseline is defined. The baseline solution should deliver the same function as the handprint solution, be used for the same purpose, be available on the same market in a specified time period and geographical location, and be assessed consistently following the LCA guidance in terms of several key factors, e.g. data quality, representativeness, system boundaries, and assumptions.

Carbon Handprint, Fig. 3 Possible contributing mechanisms to carbon handprint (Pajula et al. 2018)

If the product is entirely new on the market, the baseline has to be set to reflect the current situation without the product. However, if a (more sophisticated) product replaces a current market-available product, the conductors of the assessment have to define the baseline based on the specific customer's current product. If the customer cannot be precisely identified and, thus, the current baseline product cannot be determined directly, one must set the baseline complying with three key criteria. First, choose a market leader or a typical product in the identified reference area and time. Second, if identifying one typical product is not possible, one can use an average product in that specific region and time. As a third option, available product specifications, standards, or best available technique reference documents can be used as a baseline. This can be a justified choice, if there is an abundant amount of business-as-usual solutions or if data on the competitor's solution is difficult to attain.

Stage 2: Defining LCA Requirements

The second stage in the process covers the essential steps regarding LCA requirements. First, the functional unit of the study describes the performance of the studied product system and provides a reference on which the resulting greenhouse gas emissions are related. Second, the system boundaries defining unit processes to be included or excluded from the study are set. The system boundaries should be set consistently with the goal of the study and, therefore, always include the product's use phase by the customer. It is also important to have equal system boundaries for the baseline and the handprint solutions. Third, data needs and sources are identified. If the customer of the product can be identified in the previous stage, one should aim to use the most recent primary data from that customer. If this is not possible, statistical or average data needs to be used. However, the aim is to have data that is as representative as possible of the actual operating environment, both for the baseline and for the handprint solution.

Next, the carbon footprint calculation for the baseline solution, as well as for the handprint solution, is conducted following ISO 14067

guidance. After that, these two footprints are compared and the difference equals the carbon handprint of the product. The product that enabled this reduction gets the carbon handprint, and the carbon footprint reduction benefits the customer using that product. In some cases, the baseline solution has a lower carbon footprint than the handprint solution. Then, no carbon handprint is not created.

The final step in the carbon handprint approach focuses on communication. First, a critical review is recommended if the study is intended to be disclosed to a public audience. Second, the results of the study are to be communicated following the principles of appropriateness, clarity, credibility, and transparency – as presented in ISO 14026 (2017) and ISO 14063 (2010). Kilograms of carbon dioxide equivalents [kg CO₂eq.] per functional unit is the carbon handprint unit used for describing greenhouse gas emission reduction. However, using more informative reference unit instead the functional unit may be reasonable for better communicating the results to the audience. As carbon handprint is new as a concept, and the logic of creating a handprint differs from a footprint, the term and results can be difficult to convey. Additionally, also hindering the communication is a great deal of information and assumptions that should be acknowledged, as is the case in LCA or footprint studies too.

Summary

The lack of methods for calculating and communicating the beneficial environmental impacts of products and services has led to the development of a carbon handprint approach. The purpose of this approach is to assess and communicate the positive climate impact of products and services, thereby incentivizing responsible practices and allowing educated choices.

The core of the approach involves comparing the carbon footprint of an improved product with the carbon footprint of the baseline product and, subsequently, calculating the reduction in greenhouse gas emissions that can be achieved by using the improved product. The carbon handprint

approach is founded on the standardized life cycle assessment methodology for footprints.

Organizations can use carbon handprints to quantify the greenhouse gas reductions that their customers can achieve by using provided products. The carbon handprint can, thus, serve as a tool in communications and marketing. A company can also find out how their product qualifies in comparison to baseline products and, therefore, carbon handprints can also support decision-making and lifelong product design. Through future research, the handprint methodology may be adjusted to also cover other environmental impact categories or indicators.

Greenhouse gas (GHG) management; Mitigation measures and mechanisms

Definition

Carbon management is managing the causes and impacts of climate change, mainly via mitigation measures and mechanisms. These include implementing mechanisms from international treaties, measuring and regulating mitigation measures, reducing carbon, i.e. greenhouse gas (GHG), emissions in the atmosphere, and governing global and local policies. Even though mitigation is defined as the primary goal of carbon management, some adaptation measures need to be taken to deal with the effects of climate change. From its inception, carbon management is a multi-disciplinary and interdisciplinary global issue; therefore, carbon management requires a wealth of knowledge from various areas. The adoption of the United Nations Framework Convention on Climate Change (UNFCCC) in 1992 is the basis of international efforts. Related international treaties have led to several policy implementations on various levels. Although the energy sector is directly linked to carbon emissions and the buildings sector is the largest emitter, every sector can take measures. Each stakeholder must identify, assess, plan, and monitor their GHG emissions to reach relevant carbon goals. In this context, mitigation, economy, and policies lie at the core of carbon management.

Background

Carbon management is a multidisciplinary and interdisciplinary field. A variety of changes are linked to climate change including changes in the hydraulic cycle of the Earth, changes in sea levels, displacements of climate zones, increase in sudden climatic events, desertification, remarkable changes in glacial areas, epidemics related to temperature changes, and increase in pests. Besides, these physical changes are linked to the lives of humans and have various socio-economic effects. Understanding the entire carbon cycle requires an understanding of carbon sources, processes, and sinks. Therefore, the effect of human interventions on environmental mechanisms is not easy to determine.

The nature-based emissions – emitted during the carbon cycle – dominate the amount of carbon in the atmosphere; there were many claims that human-induced emissions are insignificant and there is no climate change or global warming, and even if there is, it is not human-induced. However, the findings of the United Nations Intergovernmental Panel on Climate Change (IPCC) show that climate change is occurring, and it is very likely caused by human-induced emissions. IPCC constantly reviews climate change science and reports its findings, and IPCC's models form the basis for unifying many diverse studies throughout the globe.

The main aim of carbon management is to decrease the total amount of carbon in the atmosphere to stabilize global temperature. Also called climate change mitigation, carbon management refers to actions that limit or reduce the amount of greenhouse gas (GHG) in the atmosphere. While various gasses play a role in climate change, the most infamous one is carbon dioxide; thus, the term “carbon emissions” is used as an alternative way to call GHG emissions. Theoretically, carbon neutrality can be reached as a net balance of zero between “emission sources” and “capture and storage”. Therefore, efforts to mitigate climate change lie in identifying their sources, utilizing more efficient or more sustainable resources, and increasing their sequestration. These processes have many interlinked facets, and current research tends to focus on integrated assessments. Here, the topic is discussed under the core headings of carbon mitigation, carbon economy, and carbon policies.

Carbon Mitigation

The cause of the climate change phenomenon has been accepted as correlating to human-induced GHG emissions. Yet there is still a need for research on climate models, so that carbon mitigation pathways that aim for a target temperature increase can be generated. The results from geophysical models largely depend upon the uncertainties of data input to the system. In time the number of relevant measurements and

accessibility to reliable data increases globally. For long-term projections, other causes of uncertainties include technological innovations, shifts in the economy, and policies. The spread of open research, open access, and data-sharing platforms and developments in information and communication technologies is making accessing and using data easier.

GHG emissions have been continuously increasing despite mitigation efforts. Moreover, the speed of growth between 2000 and 2010 was the highest in human history. The most recent relevant summary of carbon emissions, as well as drivers and trends for mitigation can be found in IPCC's Fifth Assessment Report (2014). The increase in GHG levels in the atmosphere is mainly related to the use of fossil fuel combustion and industrial processes. Therefore, at first, the target of carbon management strategies has been to regulate and possibly decrease the amount of existing carbon emissions. The first step was to increase the share of renewable energy in the energy sector, thereby decreasing the carbon intensity of the energy supply. While solar and onshore wind energy widely propagated into the market, the use of fossil fuels (coal in particular) has also increased since 2000, according to IPCC (2014).

Population growth, per capita production and consumption growth are the main drivers of GHG emissions. The carbon efficiencies of energy technologies are increasing with time. The trend of R&D budget for energy research in IEA member countries also strongly favors renewables while the share of nuclear and fossil fuels is decreasing, but the most significant increase is in energy efficiency research. However, the potential reductions of increased efficiency and other technological innovations are not reached. The "rebound effect" diminishes potential gains by triggering behavioral responses. In recent years, the overall increase in consumption, coupled with population growth, increased the total demand and related carbon emissions as a result despite reducing the energy intensity of products.

Many industries are changing their practices in accordance with the legislative requirements of reporting carbon in different scopes. The most

rapid rise is seen in emissions from international transport with logistics and smartness as primary issues. IPCC (2007) projects that the building sector can have the most impact on global emissions with the least amount of costs. This is because a 90% of reduction in projected baseline emissions is possible with less than 20US\$ per tCO₂-eq, which is possible by utilizing simple building energy efficiency and management measures. Even a 29% of reduction can be reached through behavioral changes at no cost. In addition, cities provide high mitigation opportunities since more than half of the human population is living in cities, and the city populations are increasing. However, some choices such as urban design, form, and infrastructure have long-lasting effects.

The existing cities and the life cycle of their elements must be considered in urban development. Besides, financial and institutional capacities limit what can be implemented. While embodied carbon is not a common concern, the concepts of recycling, reuse, and circularity are gaining attention and decreasing the new resource requirements and affecting related land use. With the increasing knowledge of ecosystems, making use of and strengthening ecosystem services in the desired direction, for instance, by bringing nature into cities is a prominent research topic with demonstration applications. Other research areas worth mentioning relate to smart cities, smart transportation, resilient design, circular economy, building energy management, biodesign, social responsibility, and encouraging pro-environmental behavior.

The easiest way to calculate carbon in the atmosphere is to look at human-induced energy use according to fuel type and looking at the removal of carbon from the atmosphere. Reducing the carbon from the atmosphere for mitigation is called carbon sequestration or carbon dioxide removal (CDR). In the carbon cycle, carbon is removed from the atmosphere through biological means. Carbon sinks, i.e., natural reservoirs that play a role in the carbon cycle by absorbing carbon, can be utilized for carbon sequestration; these include soil, photosynthetic organisms, and the ocean. The most common implementation

examples are afforestation or changing land use and land cover to vegetation, thus enhancing the ecosystem's capacity to sequester carbon.

Options without CDR include economic, efficiency, renewable energy, agricultural intensification, low-carbon technologies, lifestyle change, and low population growth. Van Vuuren et al. (2018) analyzed these diverse transition pathways to reach a 1.5 °C target set in the Paris Agreement and found that although these options greatly reduce the necessity for CDR, CDR is still necessary for reaching the target. Meanwhile, capturing waste carbon (by any means) is called carbon capture and storage (CCS), otherwise known as carbon capture and sequestration. The maturity of CCS technologies limits its utilization; meanwhile, areas for improvement include cost, capacity, leakage prevention, and possible effects on the environment.

Carbon Economy

Classic theories of international relations and economics are inadequate for capturing the challenges of climate change on global development (Sequeira and Reis 2019). The carbon economy is a relatively new term, since carbon trading started through market-based instruments started recently. The first instruments defined in the Kyoto Protocol emission trading schemes (ETS) include “cap-and-trade (CAT)” or “allowance” and “carbon credit.” Kyoto Protocol allows a country to redeem part of its obligations in other countries via a clean development mechanism (CDM) and joint implementation (JI). Other market instruments include “baseline and credit” and prescriptive regulation. Gillingham and Stock (2018) argue that the most economically efficient way to reduce emissions can be implemented by a Pigouvian tax for carbon so that externalities can be internalized, and markets find the most cost-effective ways without failing. However, a carbon tax is not common.

Many large corporations adopted carbon management practices (CMPs) and monitor, measure, and report their carbon emissions. Some argue that corporations use CMPs to either greenwash

or not deal with the real underlying problems about the exploitation of the environment. The literature on CMPs usually makes use of a wide range of case studies to find out which CMPs are more effective. More successful CMPs are flexible, dynamic, and in alignment with the corporation's strategy while ensuring stakeholder engagement (Mazhar et al. 2017). Yet, all evidence does not support that CMPs are successful; Doda et al. (2016) conducted the first large-scale empirical study to look at common corporate carbon management practices by using data from the Carbon Disclosure Project. They did not find enough evidence to support that common CMPs are effective and proposed three likely explanations: (1) Data reporting is nonstandard; (2) there is a possible delay between action and effect, or (3) the practices do not have enough impact.

The GHG Protocol defines scopes for GHG emissions to standardize calculations. Yet, approaches used for measuring, estimating, reporting, and verifying GHG emissions and removals are not standard, and all have limitations. For example, direct or indirect emission accounting changes the interpretation and expectations. The results of a CMP can be assessed by comparison against a “baseline” emission level. The “permanence,” i.e., its continuation till the promised carbon reduction is reached and the carbon decrease made possible with the funding (additionality) also needs consideration (Lansing 2012). The marginal cost per tCO₂-eq GHG emissions is around \$116 according to a meta-analysis of the literature while the regulatory agencies in the USA report a more conservative number of \$36 in 2007 (Di Filippo et al. 2019).

There is a strong correlation between gross domestic product (GDP) and emissions (IPCC 2014). Although there are some exceptions, a 1% GDP increase is associated with a 0.49% carbon emission increase related to fossil energy; this is mainly due to the rapid growth of some Asian countries. There is a wide range of carbon emissions for each added person according to socio-economic and geographical properties; in other words, behavior and lifestyle choices play a significant role in the amount of carbon emission per capita. While there is a 91-fold difference in

per capita emissions between the highest and lowest emitters (IPCC 2014), whether an increase in the population of high-income or low-income countries affects GHG emissions more is unclear since early stages of industrialization require higher consumption and cause associated emissions (Martínez-Zarzoso and Maruotti 2011).

Globally, low-income countries cause nearly ten times less emissions than high-income countries according to 2010 data. Yet, mitigation costs vary, and moving away from established business as usual practices can put a burden on economies, especially for low-income countries. Although there is no economic equity in costs of mitigation, mitigation efforts themselves provide more cobenefits for developing countries: improvement in indoor air quality and related health benefits; decrease in the energy requirements and related economic, infrastructure, energy security, and accessibility gains; and alternative employment and economic opportunities. These cobenefits are difficult to assess, and adverse side effects are also possible. For instance, a replacement technology can decrease carbon dioxide but cause other GHG emissions.

Carbon Policies

Policies affect all implementations, key drivers, and barriers to mitigation, even though carbon mitigation consists of several complex and inter-related issues. The basic international legal instrument against climate change is the United Nations Framework Convention on Climate Change (UNFCCC), which aimed to “stabilize the GHG concentrations in the atmosphere” and was adopted in 1992 during the Earth Summit. The UNFCCC required its Parties to make a national inventory of their GHG emissions and removals for 1990 data. It also mentioned “common but differentiated responsibilities” according to the economic development of countries (UNFCCC 1992).

There have been many international meetings and treaties in related fields within UNFCCC; Fig. 1 shows the historically significant points in time for carbon management policies, from the industrial revolution until 2020. After the first claims of human-induced climate change at the end of the nineteenth century until the establishment of UNFCCC has been the period for debates

Carbon Management, Fig. 1 Historically significant points for carbon management policies

and preparation of scientific basis related to carbon. Later, the legal framework was established, through which either legally binding or voluntary targets were set for implementation through many agreements, the most significant of which are the Kyoto Protocol and the Paris Agreement.

The Kyoto Protocol, adopted in 1997, laid out legally binding targets for the six GHG listed in its Annex A. The Protocol aimed to regulate and decrease emissions; thus, it assigned specific mitigation targets to countries according to their economic development. In addition to setting targets for carbon emissions, the Kyoto Protocol introduced an economical mechanism. Other significant meetings and developments happened before the second phase of the Kyoto Protocol entered into force. While the outlook that sees economic growth and environmental degradation as mutually exclusive was cast off, new targets and economic mechanisms were not widely agreed upon until the Paris Agreement in 2015.

The Paris Agreement aimed to keep the long-term “increase in global average temperature to well below 2 °C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5 °C above preindustrial levels” in the twenty-first century. Each country had the responsibility to set their own goals and roadmaps and report their nationally determined contributions (NDCs) to mitigation efforts within a very flexible mechanism, which allowed for making course corrections to reach targets within time. The Agreement supported capacity building and transparency with new technological and financial resources, including voluntary cooperation and nonmarket approaches that lead to mitigation outcomes (UNFCCC 2015).

While some claim that 1.5 °C is a well-thought target, some claim that it is ambitious or impossible to reach and criticize the accountability mechanism of the Paris Agreement with not promoting compliance (Rogelj et al. 2016). Mechanisms formed by international treaties can be either obligatory or voluntary. However, countries cannot manage each other’s internal affairs; therefore, free riding becomes an issue. To solve this issue, Nordhaus (2015) proposes

that countries create a climatic club, with trade penalties for nonparticipants. Buchholz and Sandler (2017) point out that environmental leadership usually encourages free riding instead of following the leader. Another solution can be international coordination by a big and powerful coalition, such as the European Union.

The Paris Agreement also considers the issues of adaptation, resilience, averting loss and damage, and climate change education that also need consideration in addition to mitigation goals. Adaptation is an approach to reduce the vulnerability of the expected effects of climate change by adjusting to a new normal. Adaptation does not only encompass reactions to minimize the impacts of the new system but also looks for opportunities to maximize benefits from the new situation. While Bayramoglu et al. (2018) relate mitigation with public good and adaptation with private good, they also show that adaptation strategies can complement and enhance the effects of mitigation efforts.

International agreements must be translated to come into effect so that implementation is possible at other levels. Besides adoption into the national legal system, domestic policies and local legislative measures are necessary. In other words, the law must be consolidated. Effective action at a local level and community engagement are vital. Grassroots activities can emerge when the governmental view is not in line with taking mitigation options. There are prescriptive legislation or more flexible mechanisms, in which a polluter can choose from options. Which mechanisms perform best, to regulate mitigation is unclear at the moment. Therefore, the performance of mitigation actions must be assessed for a low-carbon future.

Summary

Carbon management aims to utilize and develop appropriate resources and methods to preserve the future well-being and prosperity of humanity by mitigating climate change. It is a rapidly growing research field including modeling and assessing
